# **Compiling Techniques**

Lecture 4: Automatic Lexer Generation

## Automatic Lexer Generation

- Starting from a collection of regular expressions (RE) we automatically generate a Lexer
- We use finite state automata (FSA) for the construction

# A Finite State Automata

A finite state automata is defined by:

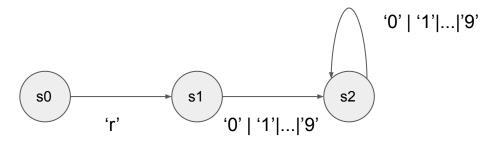

- **S**, a finite set of states
- Σ, an alphabet, or character set used by the recogniser
- δ(s, c), a transition function (takes a state and a character and returns new state)
- **s0**, the initial or start state
- **SF**, a set of final states (a stream of characters is accepted iif the automata ends up in a final state)

#### Finite State Automata for Regular Expression

Example: register names

register ::= 'r' ('0'|'1'|...|'9') ('0'|'1'|...|'9')\*

The RE (Regular Expression) corresponds to a recognizer (or a finite state automata):

## Table encoding and skeleton code

To be useful a recognizer must be turned into code

'0' | '1'|...|'9'

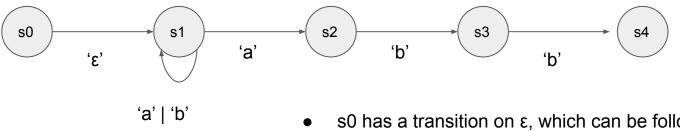

δ	ʻr'	'0' '1'  '9'	others
s0	s1	error	error
s1	error	s2	error
s2	error	s2	error

Skeleton recogniser c = next character() state = "s0" while c := EOF: state =  $\delta(s, c)$ c = next character() if (state final): return success else: return error

## Non-Determinism

#### **Deterministics Finite Automaton**

Each RE corresponds to a Deterministic Finite Automaton (DFA). However, it might be *hard to construct directly*.

- What about an RE such as (a|b)\* abb ?
- s0 has a transition on ε, which can be followed without consuming an input character.
- s1 has two transitions on a
- This is a non-deterministic finite automaton (NFA)

# Non-deterministic vs deterministic finite automata

Deterministic finite state automata (DFA):

- All edges leaving the same node have distinct labels
- There is no transition

Non-deterministic finite state automata (NFA):

- Can have multiple edges with the same label leaving from the same node
- Can have ε transition

This means we *might have to backtrack* 

# Automatic Lexer Generation

It is possible to systematically generate a lexer for any regular expression.

This can be done in three steps:

- 1. regular expression (RE)  $\rightarrow$  non-deterministic finite automata (NFA)
- 2. NFA  $\rightarrow$  deterministic finite automata (DFA)
- 3. DFA  $\rightarrow$  generated lexer

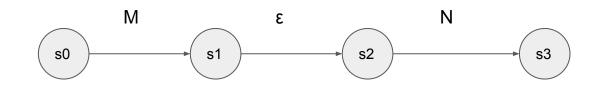

#### 1st step: $RE \rightarrow NFA$ (Ken Thompson, CACM, 1968)

'x'

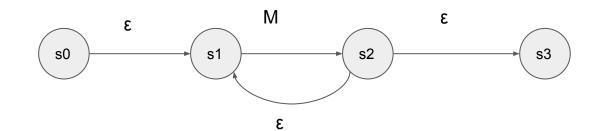

'X' M | N Μ s0 s1 3 s1 s2 3 s5 s0 [M] 3 3 3 s3 s4 s0 Ν s1 Μ

## 1st step: $RE \rightarrow NFA$ (Ken Thompson, CACM, 1968)

MN

М+

# Step 2: NFA $\rightarrow$ DFA

Executing a non-deterministic finite automata requires backtracking, which is inefficient. To overcome this, we need to construct a DFA from the NFA.

The main idea:

- We build a DFA which has one state for each set of states the NFA could end up in.
- A set of state is final in the DFA if it contains the final state from the NFA.
- Since the number of states in the NFA is finite (n), the number of possible sets of states is also finite (maximum 2<sup>n</sup>, hint: state encoded as binary vectors).

# From NFA to DFA

Assuming the state of the NFA are labelled si and the states of the DFA we are building are labelled qi.

We have two key functions:

- reachable(si ,  $\alpha$ ) returns the set of states reachable from si by consuming character  $\alpha$
- closure(si) returns the set of states reachable from si by ε (e.g. without consuming a character)

# Algorithm

#### The Subset Construction algorithm (Fixed point iteration)

```
\begin{array}{l} q_0 = \epsilon \text{-} \textit{closure}(s_0); \ Q = \{q_0\}; \ \text{add} \ q_0 \ \text{to} \ \text{WorkList} \\ \text{while} \ (\text{WorkList not empty}) \\ \text{remove} \ q \ \text{from} \ \text{WorkList} \\ \text{for each} \ \alpha \in \Sigma \\ \textit{subset} = \epsilon \text{-} \textit{closure}(\textit{reachable}(q, \alpha)) \\ \delta(q, \alpha) = \textit{subset} \\ \text{if} \ (\textit{subset} \notin Q) \ \text{then} \\ \text{add} \ \textit{subset} \ \text{to} \ Q \ \text{and} \ \text{to} \ \text{WorkList} \end{array}
```

#### The algorithm (in English)

- Start from start state  $s_0$  of the NFA, compute its  $\epsilon$ -closure
- Build subset from all states reachable from  $q_0$  for character lpha
- $\bullet\,$  Add this subset to the transition table/function  $\delta\,$
- If the subset has not been seen before, add it to the worklist
- Iterate until no new subset are created

# NFA for a(b|c)\*

$a(b c)^*$	$(S_{0} \xrightarrow{a} (S_{1} \xrightarrow{\epsilon} (S_{2} \xrightarrow{\epsilon} (S_{3} \xrightarrow{\epsilon} (S_{4} \xrightarrow{b} (S_{5} \xrightarrow{\epsilon} (S_{5} \xrightarrow{\epsilon} (S_{7} \xrightarrow{s_{6} (S_{7} \xrightarrow{\epsilon} (S_{7} \xrightarrow{s_{7} (S_{7} \xrightarrow{\epsilon} (S_{7} \xrightarrow{\epsilon} (S_{7} \xrightarrow{s_{7} (S_{7} \xrightarrow{\epsilon} (S_{7} \xrightarrow{s_{7} (S_{7} \xrightarrow{\epsilon} (S_{7} \xrightarrow{s_{7} (S_{7} (S_{7} \xrightarrow{s_{7} (S_{7} (S_{7} \xrightarrow{s_{7} (S_{7} (S_{7} (S_{7} \xrightarrow{s_{7} (S_{7} (S_{7$						
			$\epsilon$ -closure(reachable( $q, \alpha$ ))				
		NFA states	а	b	С		
	$q_0$	<i>s</i> 0	$q_1$	none	none		
	$q_1$	$s_1, s_2, s_3,$	none	<i>q</i> <sub>2</sub>	<i>q</i> <sub>3</sub>		
		<i>s</i> <sub>4</sub> , <i>s</i> <sub>6</sub> , <i>s</i> <sub>9</sub>					
	$q_2$	<i>s</i> <sub>5</sub> , <i>s</i> <sub>8</sub> , <i>s</i> <sub>9</sub> ,	none	<i>q</i> <sub>2</sub>	<i>q</i> <sub>3</sub>		
		<i>s</i> <sub>3</sub> , <i>s</i> <sub>4</sub> , <i>s</i> <sub>6</sub>					
	<i>q</i> 3	<i>s</i> <sub>7</sub> , <i>s</i> <sub>8</sub> , <i>s</i> <sub>9</sub> ,	none	<i>q</i> <sub>2</sub>	<i>q</i> <sub>3</sub>		
		<i>s</i> <sub>7</sub> , <i>s</i> <sub>8</sub> , <i>s</i> <sub>9</sub> , <i>s</i> <sub>3</sub> , <i>s</i> <sub>4</sub> , <i>s</i> <sub>6</sub>					

# DFA for a(b|c)\*

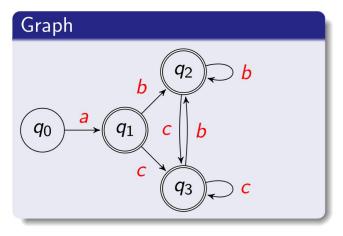

Table encoding						
	а	b	С			
$q_0$	$q_1$	error	error			
$q_1$	error	$q_2$	<i>q</i> 3			
<i>q</i> <sub>2</sub>	error	$q_2$	<i>q</i> 3			
<i>q</i> 3	error	$q_2$	<i>q</i> <sub>3</sub>			

- Smaller than the NFA
- All transitions are deterministic (no need to backtrack!)
- Could be even smaller

(see EaC§2.4.4 Hopcroft's Algorithm for minimal DFA)

• Can generate the lexer using skeleton recogniser seen earlier

#### What can be so hard

Poor language design can complicate lexing

- PL/I does not have reserved words (keywords): if (cond) then then = else; else else = then
- In Fortran & Algol68 blanks (whitespaces) are insignificant: do 10 i = 1,25 ~= do 10 i = 1,25 (loop, 10 is statement label) do 10 i = 1.25 ~= do10i = 1.25 (assignment)
- In C,C++,Java string constants can have special characters: newline, tab, quote, comment delimiters, . . .

# **Building a Lexer**

The important point:

- All this technology lets us automate lexer construction
- Implementer writes down regular expressions
- Lexer generator builds NFA, DFA and then writes out code
- This reliable process produces fast and robust lexers

For most modern language features, this works:

- As a language designer you should think twice before
- introducing a feature that defeats a DFA-based lexer
- The ones we have seen (e.g. insignificant blanks, non-reserved keywords) have not proven particularly useful or long lasting
