

# Compiling Techniques

Lecture 10: Type Analysis

# Types and Type System

*A type system is a tractable syntactic method for proving the absence of certain program behaviors by classifying phrases according to the kinds of values they compute.*

**Benjamin Pierce** Types and Programming Languages

# Types and Type System

We operate on the AST

*A type system is a tractable **syntactic method** for proving the absence of certain program behaviors by classifying phrases according to the kinds of values they compute.*

**Benjamin Pierce** Types and Programming Languages

# Types and Type System

We operate on the AST

Detecting of Semantic Errors

*A type system is a tractable **syntactic method** for **proving the absence of certain program behaviors** by classifying phrases according to the kinds of values they compute.*

**Benjamin Pierce** Types and Programming Languages

# Types and Type System

We operate on the AST

Detecting of Semantic Errors

*A type system is a tractable syntactic method for proving the absence of certain program behaviors by classifying phrases according to the kinds of values they compute.*

**Benjamin Pierce** Types and Programming Languages

That's what we call **Types**

# ChocoPy Type System

- ChocoPy is a *statically typed* language
  - We verify that programs are well-typed by analyzing the program's syntax without executing it
- ChocoPy is a *strongly typed* language
  - Programs with type errors are rejected and there are no implicit type conversions
- ChocoPy has *subtyping*
  - Types form a hierarchy and a value of a subtype can safely be used in a context where a value of the supertype is expected

# Types of ChocoPy

- The grammar of ChocoPy contains the syntax of the following types:
  - `int` - representing integer values
  - `bool` - representing the two values `True` and `False`
  - `str` - representing strings
  - `object` - the *top type*, i.e., every value has this type
  - `[T]` - representing a list with elements of type `T`, where `T` is itself a type
- ChocoPy defines three more types that cannot be written by the user:
  - `<Empty>` - representing an empty list
  - `<None>` - representing the value `None`
  - $\perp$  - the *bottom type*, i.e., the type that has no value

```
...  
type := type_name | `[` type `]`  
type_name := int | bool | str | object  
...
```

# Type Hierarchy of ChocoPy

- The types form a hierarchy:

- The type hierarchy is precisely defining by a *subtyping relationship* ( $\leq$ ), where:
  - $T \leq T$  for all types  $T$
  - $T \leq \text{object}$  for all types  $T$
  - $\perp \leq T$  for all types  $T$
  - If none of the three cases above apply, then the types are not related by subtyping, for example: `[int]` and `[bool]` are not related by subtyping

# Type Checking

- The type checking process verifies and enforces the **type system**
- The type system is defined by a set of formal **typing rules** that describe under what conditions a syntactic construct is well-typed (*“has a valid type”*)
- To perform **type checking**, we process a syntactically well-formed program and apply the typing rules to check if we can justify that every definition, statement, and expression is well-typed

# Typing rules are inference rules

- A **typing rule** is a form of a logical inference rule

- We write a typing rule like this:

$$\frac{\begin{array}{c} \vdots \\ \hline \end{array}}{O \vdash e : T} \quad [\text{NAME}]$$

- Each typing rule contains:

- a **[NAME]**,
  - zero, one, or multiple **premises** above the line,
  - a **conclusion** below the line.
- The rule states, that if the premises are true, then the conclusion is true as well.  
In other words: to check the conclusion, we must check that all premises are true

# Typing Judgement

- $\Gamma \vdash e : T$  is a *typing judgement*, where the turnstile symbol ( $\vdash$ ) separates the *typing environment* on the left from the proposition on the right.
- This judgement should be read as:

*"In the type environment  $\Gamma$  the expression  $e$  is well typed and has type  $T$ "*

- Why do we need a typing environment?
- Why can't we just say: *"The expression  $e$  is well typed and has type  $T$ "*?

# Typing Environment

- Consider:  $\vdash x + 4 : \text{int}$  Is this a valid typing judgement?
- We cannot say without knowing the type of  $x$ !
  - If  $x$  has type `int`, then the judgement seems valid
  - If  $x$  has not the type `int`, then the judgement seems wrong
- The *typing environment* records the type of all variables and functions that are in scope when type checking a definition, statement, or expression
- Given a typing environment, we can always conclude if a typing judgement is valid:

$$\{x: \text{int}\} \vdash x + 4 : \text{int}$$

# Typing Environment of ChocoPy

- For type checking ChocoPy, we use a *local environment*  $\mathcal{O}$  that contains:
  - The types of all variables in scope  
We write  $\mathcal{O}(v) = T$  to indicate that variable  $v$  is in the local environment and has type  $T$
  - Information about all functions in scope  
We write  $\mathcal{O}(f) = \{T_1 \times \dots \times T_n \rightarrow T_o; x_1, \dots, x_n; v_1: T'_1, \dots, v_m: T'_m\}$  to indicate that function  $f$  is in the local environment and
    - has a function type with
      - $T_1, \dots, T_n$  the types of the function parameters
      - $T_o$  the function return type
    - has function parameters with names  $x_1, \dots, x_n$
    - has identifiers and types  $v_1: T'_1, \dots, v_m: T'_m$  of variables declared in the body of  $f$
- We also record the return type  $R$  of the current function in the environment

# First ChocoPy Typing Rules

$$\frac{}{0, R \vdash \text{False} : \text{bool}} \quad [\text{BOOL-FALSE}]$$

# First ChocoPy Typing Rules

$$\frac{}{O, R \vdash \text{False} : \text{bool}} \quad [\text{BOOL-FALSE}]$$

*“There is no premise that must be true, so we can directly conclude that in the type environment  $O$  and  $R$  the expression **False** is well typed and has type **bool**”*

# First ChocoPy Typing Rules

$$\frac{}{O, R \vdash \text{False} : \text{bool}} \quad [\text{BOOL-FALSE}]$$

*“There is no premise that must be true, so we can directly conclude that in the type environment  $O$  and  $R$  the expression **False** is well typed and has type **bool**”*

$$\frac{}{O, R \vdash \text{True} : \text{bool}} \quad [\text{BOOL-TRUE}]$$

# First ChocoPy Typing Rules

$$\frac{}{O, R \vdash \text{False} : \text{bool}} \quad [\text{BOOL-FALSE}]$$

*“There is no premise that must be true, so we can directly conclude that in the type environment  $O$  and  $R$  the expression **False** is well typed and has type **bool**”*

$$\frac{}{O, R \vdash \text{True} : \text{bool}} \quad [\text{BOOL-TRUE}]$$

*“There is no premise that must be true, so we can directly conclude that in the type environment  $O$  and  $R$  the expression **True** is well typed and has type **bool**”*

# First ChocoPy Typing Rules

$$\frac{0, R \vdash e_1 : \text{bool} \quad 0, R \vdash e_2 : \text{bool}}{0, R \vdash e_1 \text{ and } e_2 : \text{bool}} \quad [\text{AND}]$$

*“If  $e_1$  has type **bool** in the type environment  $0$  and  $R$ , and if  $e_2$  has type **bool** in the same type environment  $0$  and  $R$ , then we can conclude that in the same type environment  $0$  and  $R$  the expression  $e_1$  and  $e_2$  is well typed and has type **bool**”*

# Example of Type Checking
