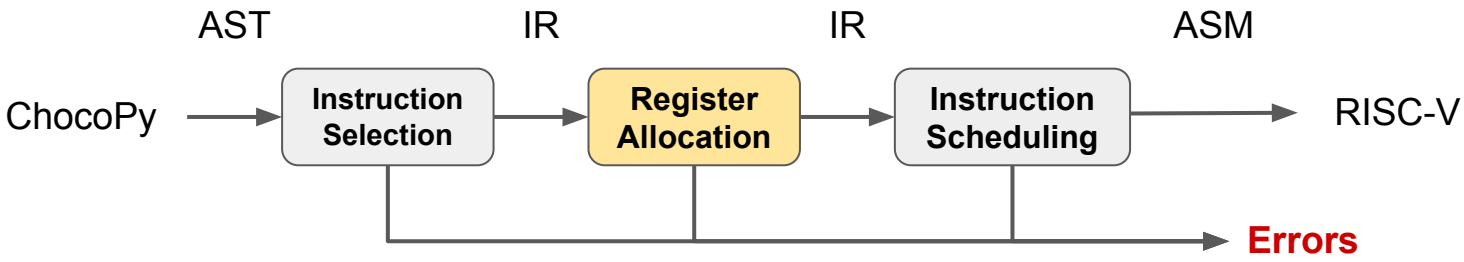
Register Allocation



Introduction

This lecture:

- Local Allocation - spill code
- Global Allocation based on graph colouring
- Techniques to reduce spill code

Register Allocation

- Physical machines have limited number of registers
- Scheduling and selection typically assume infinite registers
- Register allocation and assignment from infinite to k registers

- Produce correct code that uses k (or fewer) registers
- Minimise added loads and stores
- Minimise space used to hold spilled values
- Operate efficiently:
  - $O(n)$, $O(n^2)$, but not $O(2^n)$

Register Allocation: Definitions

Allocation vs Assignment:

- *Allocation* is deciding which values to keep in registers
- *Assignment* is choosing specific registers for values

Liveness

A value is live from its definition to its last use.

Interference

Two values cannot be mapped to the same register wherever they are both live. Such values are said to **interfere**.

Live Range

The live range of a value is the set of statements at which it is live. A live range may be conservatively overestimated (e.g, just begin → end)

Register Allocation: Definitions

Spilling

Spilling saves a value from a register to memory.
That register is then free - Another value often loaded

Requires F registers to be reserved.

Clean and dirty values

A previously spilled value is **clean** if not changed since last spill.
Otherwise it is **dirty**.

A clean value can be spilled without a new store instruction.

Local Register Allocation

Register allocation only on basic block.

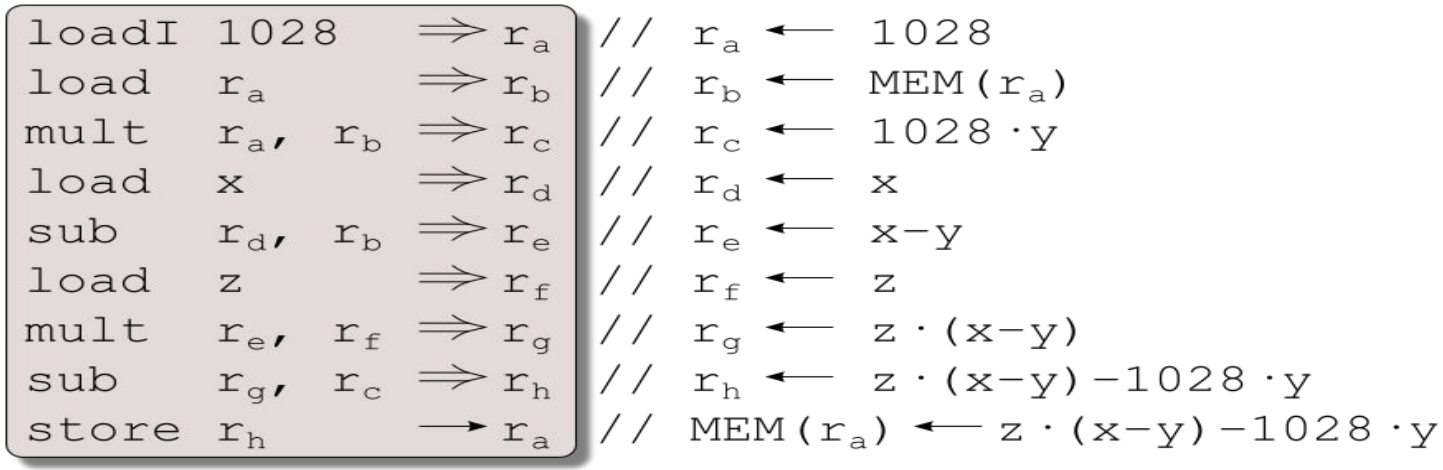
Let MAXLIVE be the maximum, over each instruction i in the block, of the number of values (pseudo-registers) live at i.

- If MAXLIVE ≤ k, allocation should be easy
- If MAXLIVE ≤ k, no need to reserve F registers for spilling
- If MAXLIVE > k, some values must be spilled to memory
- If MAXLIVE > k, need to reserve F registers for spilling

Two main forms:

- Top down
- Bottom up

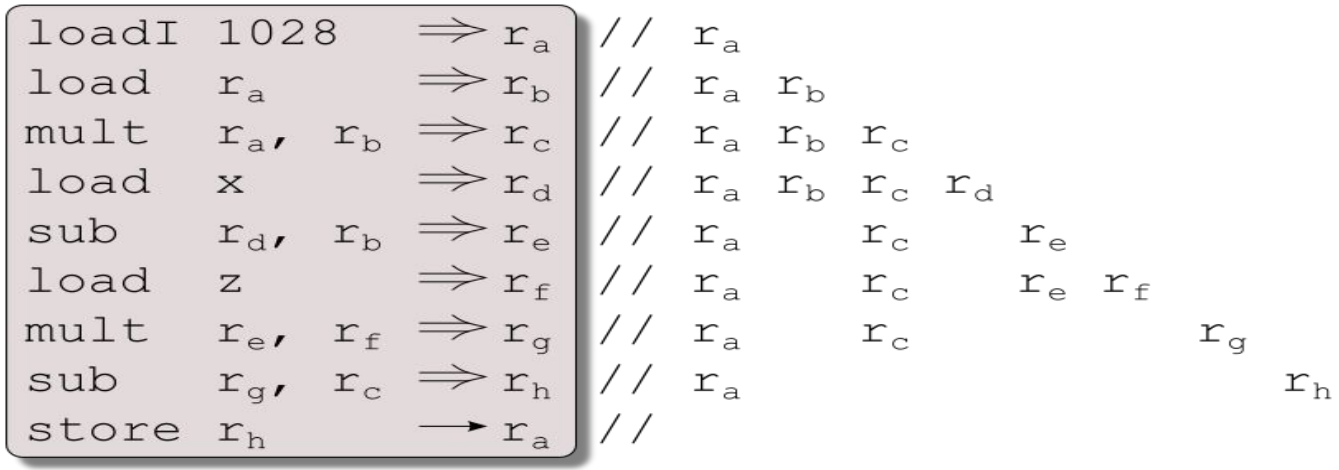
Local Register Allocation: MAXLIVE



Local Register Allocation: MAXLIVE

Example MAXLIVE computation

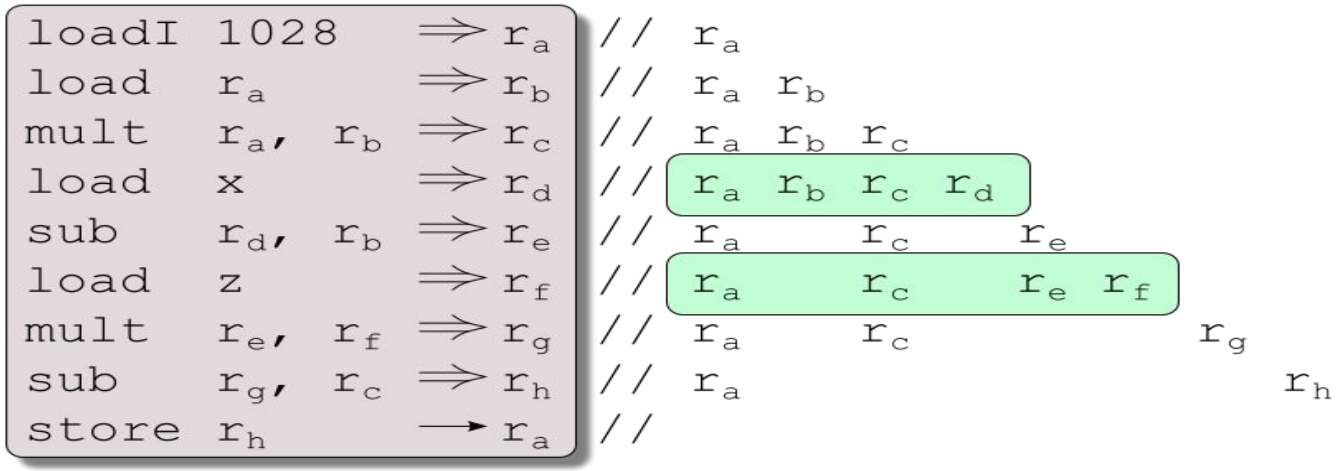
Live registers



Local Register Allocation: MAXLIVE

Example MAXLIVE computation

MAXLIVE is 4



Local register allocation: Top Down

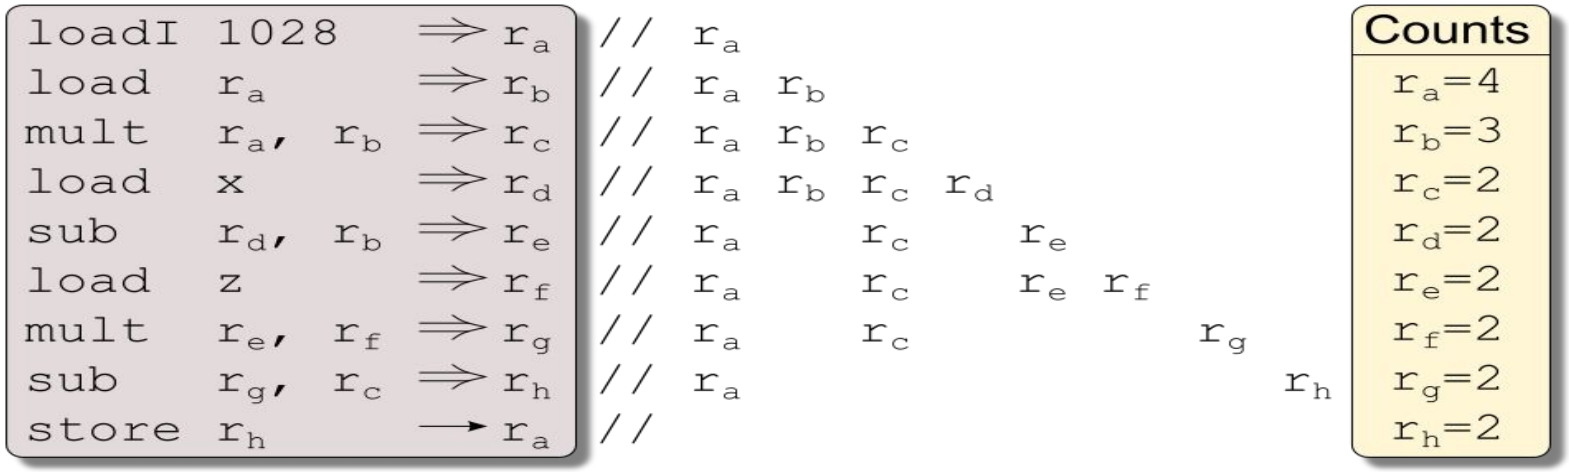
Algorithm:

- If number of values > k
  - Rank values by occurrences
  - Allocate first k - *F* values to registers
  - Spill other values

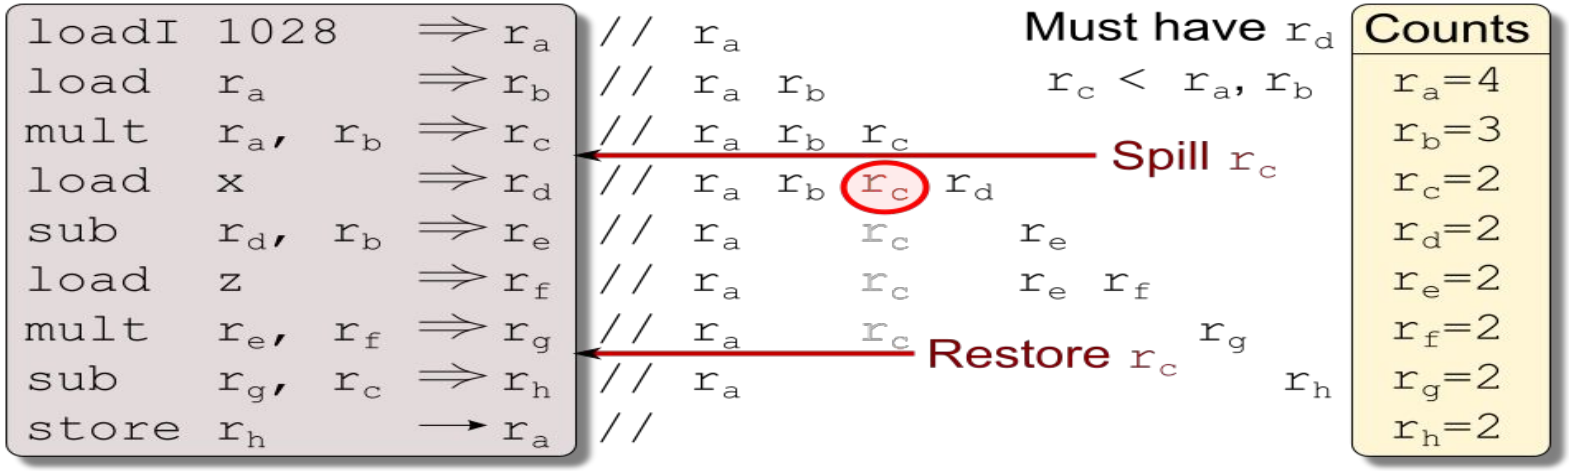
Local register allocation: top down

Example top down

Usage counts



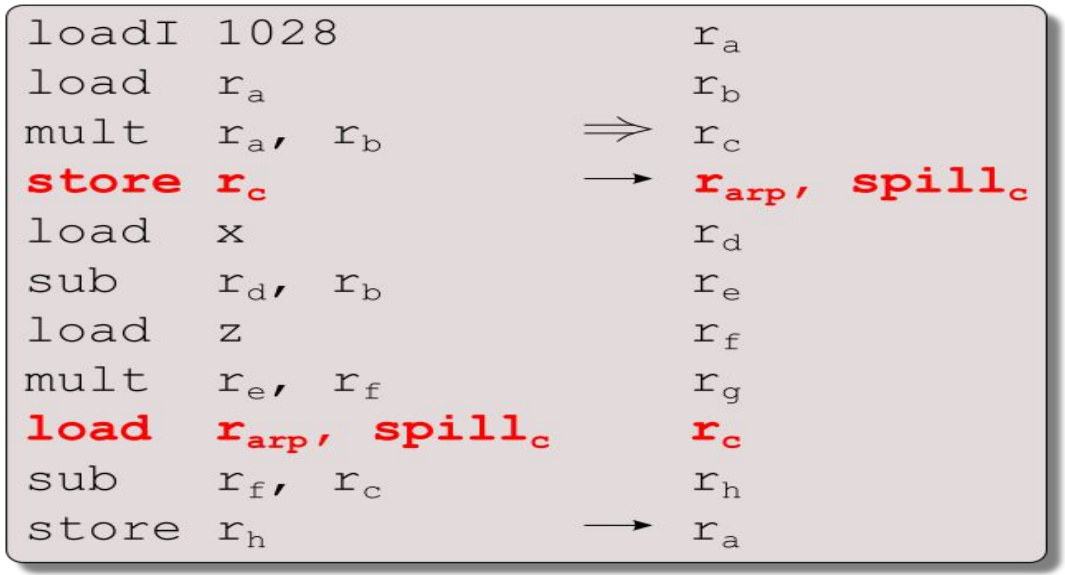
Local register allocation: Top Down



Local Register Allocation: Top down

Example top down

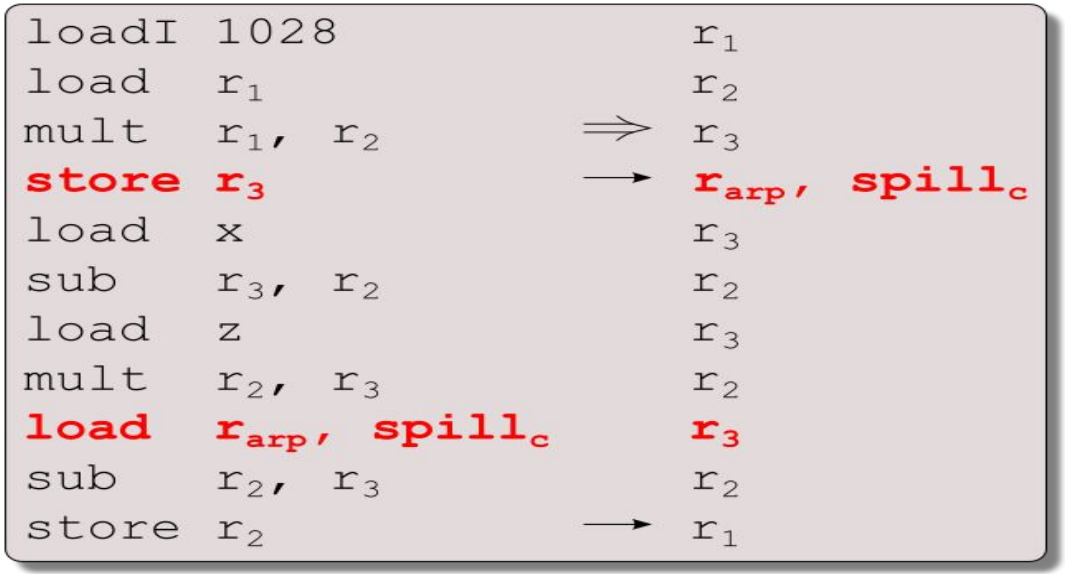
Spill code inserted



Local register allocation: Top Down

Example top down

Register assignment straightforward



Local register allocation: Bottom Up

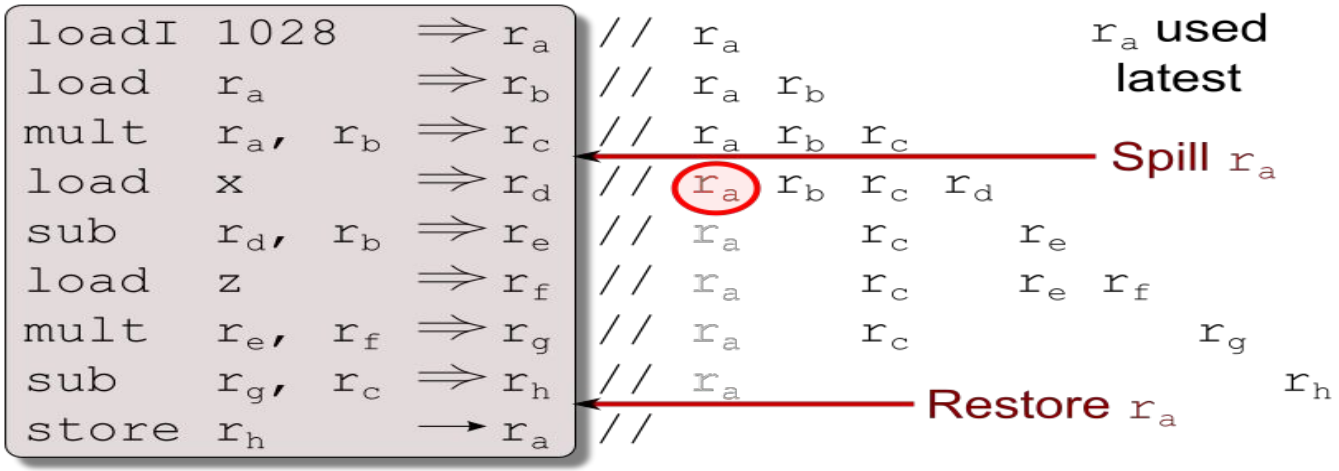
Algorithm:

- Start with empty register set
- Load on demand
- When no register is available, free one

Replacement:

- Spill the value whose next use is farthest in the future
- Prefer clean value to dirty value

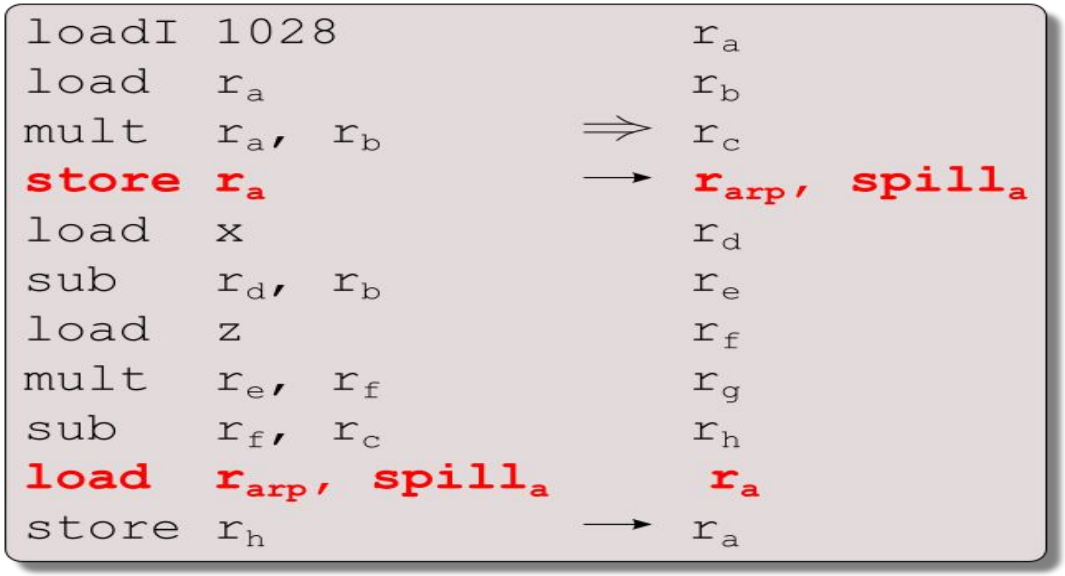
Local register allocation: Bottom Up



Local register allocation: Bottom Up

Example bottom up

Spill code inserted



Global register allocation

Local allocation does not capture reuse of values across multiple blocks

Most modern, global allocators use a graph-colouring paradigm

- Build a "**conflict graph**" or "**interference graph**"
  - Data flow based liveness analysis for interference
- Find a **k-colouring** for the graph, or change the code to a nearby problem that it can k-colour
- NP-complete under nearly all assumptions[1]

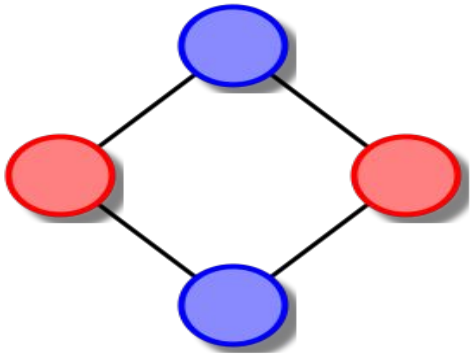
[1] Local allocation is NP-complete with dirty vs clean

Global register allocation: algorithm sketch

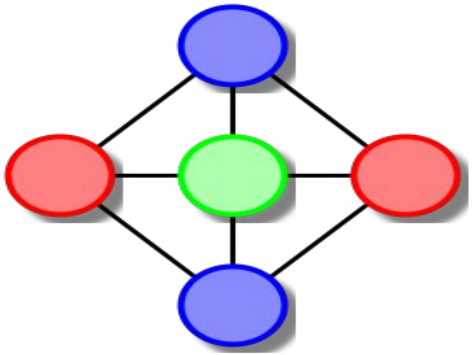
- From live ranges construct an interference graph
- Colour interference graph so that no two neighbouring nodes have same colour
- If graph needs more than k colours - transform code
  - Coalesce merge-able copies
  - Split live ranges
  - Spill
- Colouring is NP-complete so we will need heuristics
- Map colours onto physical registers

Global register allocation: Graph Coloring

A graph G is said to be **k-colourable** if the nodes can be labeled with integers 1 ... k so that no edge in G connects two nodes with the same label



2-colourable



3-colourable

Global register allocation: Interference Graph

The interference graph, $G = (N, E)$

- Nodes in G represent values, or live ranges
- Edges in G represent individual interferences
- $\forall x, y \in N, x \rightarrow y \in E$ *iff* x and y interfere

A *k-colouring* of G can be mapped into an allocation to k registers

Two values interfere wherever they are both live
Two live ranges interfere if their values interfere at any point

Global register allocation: Coloring the Register Graph

- Degree[3] of a node (n°) is a loose upper bound on colourability
- Any node, n, such that n° < k is always trivially k-colourable
  - Trivially colourable nodes cannot adversely affect the colourability of neighbours
  - Can remove them from graph
  - Reduces degree of neighbours - may be trivially colourable
- If left with any nodes such that n° ≥ k spill one
  - Reduces degree of neighbours - may be trivially colourable

Global register allocation: Chaitin's Algorithm

1. While ∃ vertices with < k neighbours in G
   - Pick any vertex n such that n° < k and put it on the stack
   - Remove n and all edges incident to it from G
2. If G is non-empty (n° >= k, ∃ n ∋ G) then:
   - Pick vertex n (heuristic), spill live range of n
   - Remove vertex n and edges from GI, put n on "spill list"
   - Goto step 1
3. If the spill list is not empty, insert spill code, then rebuild the interference graph and try to allocate, again
4. Otherwise, successively pop vertices of the stack and colour them in the lowest colour not used by some neighbour

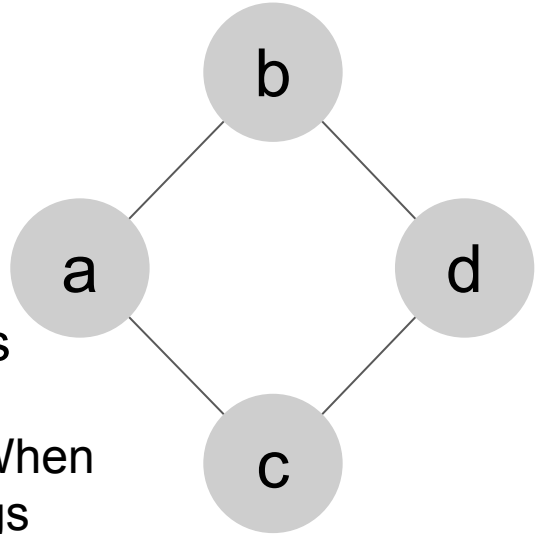
Global Register Allocation: Optimistic Colouring

If Chaitin's algorithm reaches a state where every node has k or more neighbours, it chooses a node to spill.

Example of Chaitin overzealous spilling
k = 2
Graph is 2-colourable
Chaitin must immediately spill one of these nodes



Briggs said, take that same node and push it on the stack! When you pop it off, a colour might be available for it! Chaitin-Briggs algorithm uses this to colour that graph

Global register allocation: Chaitin-Briggs algorithm

- While $\exists$ vertices with < k neighbours in G
  - Pick any vertex n such that n° < k and put it on the stack
  - Remove n and all edges incident to it from GI
- If G is non-empty (n° >= k, $\forall n \in G$) then:
  - Pick vertex n (heuristic) (Do not spill)
  - Remove vertex n from GI, put n on stack (Not spill list)
  - Goto step 1
- Otherwise, successively pop vertices off the stack and colour them in the lowest colour not used by some neighbour
  - If some vertex cannot be coloured, then pick an uncoloured vertex to spill, spill it, and restart at step 1

Global register allocation: Spill Candidates

- Minimise spill cost/degree
- Spill cost is the loads and stores needed. Weighted by scope - i.e. avoid inner loops
- The higher the degree of a node to spill the greater the chance that it will help colouring
- Negative spill cost load and store to same memory location with no other uses
- Infinite cost - definition immediately followed by use. Spilling does not decrease live range

Global Register Allocation: Alternative Spilling

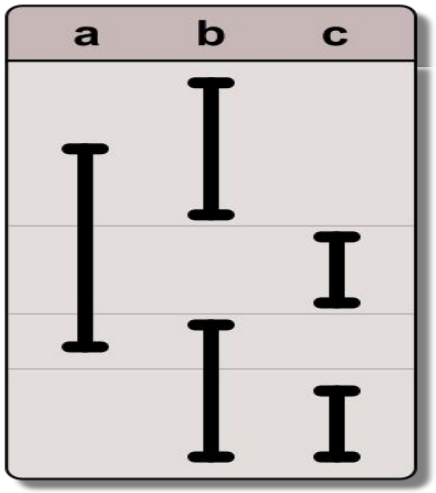
- Splitting live ranges
- Coalesce

Global Register Allocation: Live Range Splitting

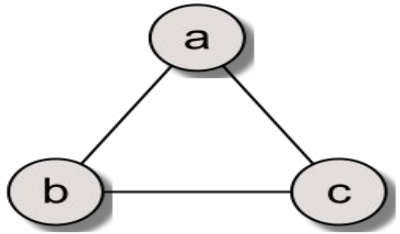
- A whole live range may have many interferences, but perhaps not all at the same time
- Split live range into two variables connected by copy
- Can reduce degree of interference graph
- Smart splitting allows spilling to occur in “cheap” regions

Global register allocation

Splitting example: Non contiguous live ranges - cannot be 2 coloured



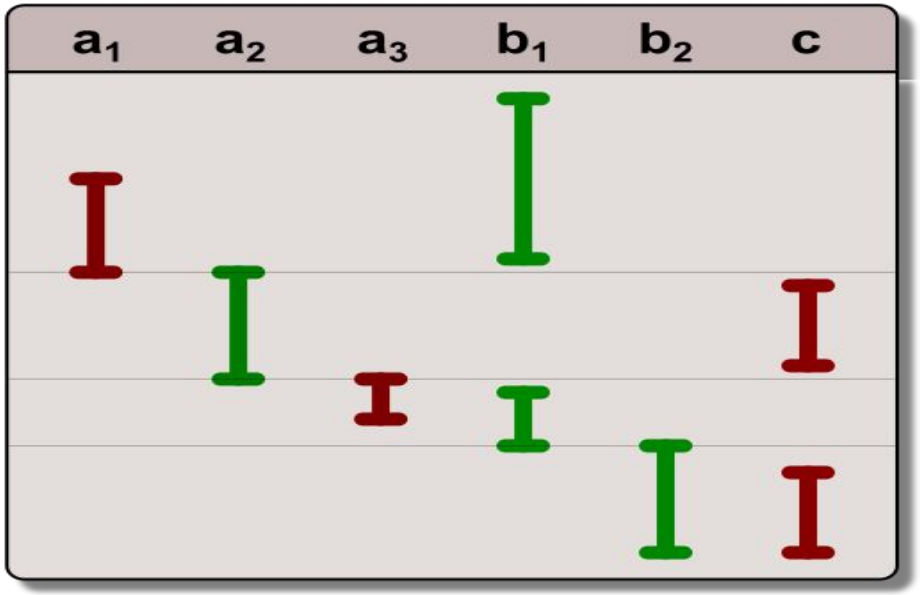
Live ranges



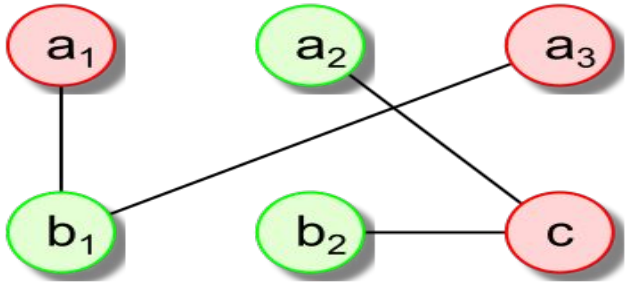
Interference Graph

Global Register Allocation: Live Range Splitting

Splitting example: Non contiguous live ranges - can be 2 coloured



Live ranges



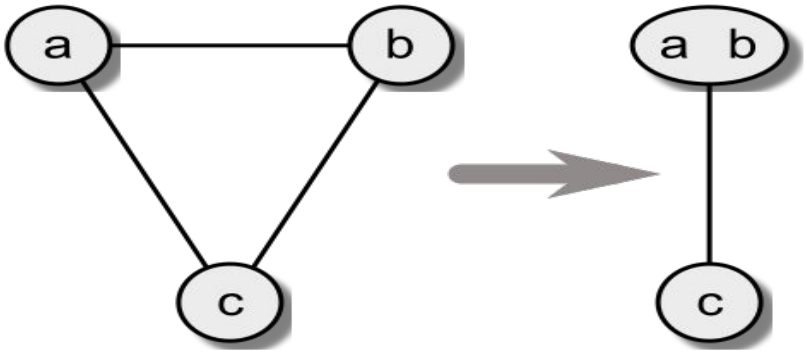
Interference Graph

Global register allocation: Coalescing

If two ranges don't interfere and are connected by a copy coalesce into one – opposite of splitting. Reduces degree of nodes that interfered with both

If $x := y$ *and* $x \rightarrow y \in G_I$ *then can combine* LR_x *and* LR_y

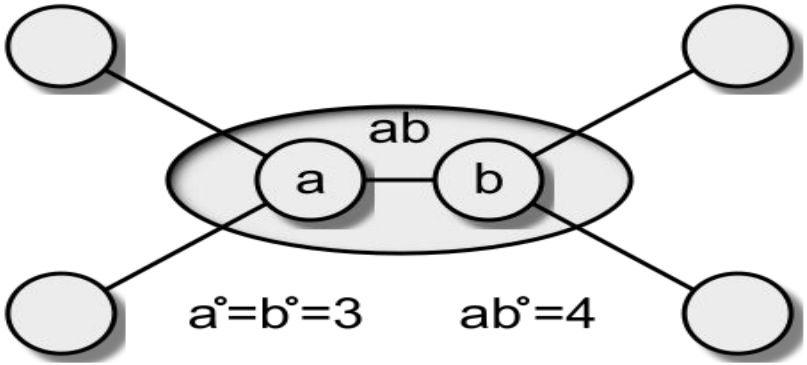
- Eliminates the copy operation
- Reduces degree of LRs that interfere with both *x* and *y*
- If a node interfered with both before, coalescing helps
- As it reduces degree, often applied before colouring takes place



Global register allocation: Coalescing

Coalescing can make the graph harder to color

- Typically, LR_{xy} ° > *max* (LR_x °, LR_y °)
- If *max* (*LRx* °, *LRy* °) < *k* and *k* < LR_{xy} ° then LR_{xy} might spill, while LR_x and LR_y would not spill



Global register allocation: Coalescing

Observation led to conservative coalescing

1. Conceptually, coalesce x and y iff $x \rightarrow y \in G_I$ and $LR_{xy}{}^{\circ} < k$
2. We can do better
   - Coalesce LR_x and LR_y iff LR_{xy} has < k neighbours with degree > k
   - Only neighbours of “significant degree” can force LR_{xy} to spill
3. Always safe to perform coalesce
   - Cannot introduce a node of non-trivial degree
   - Cannot introduce a new spill

Global register allocation: Other Approaches

- Top-down uses high level priorities to decide on colouring
- Hierarchical approaches - use control flow structure to guide allocation
- Exhaustive allocation - go through combinatorial options - very expensive but occasional improvement
- Re-materialisation - if easy to recreate a value do so rather than spill
- Passive splitting using a containment graph to make spills effective
- Linear scan - fast but weak; useful for JITs

Global register allocation: Ongoing work

- Eisenbeis et al examining optimality of combined reg alloc and scheduling. Difficulty with general control-flow
- Partitioned register sets complicate matters. Allocation can require insertion of code which in turn affects allocation.
- Leupers investigated use of genetic algs for TM series partitioned reg sets.
- New work by Fabrice Rastello and others. Chordal graphs reduce complexity
- As latency increases see work in combined code generation, instruction scheduling and register allocation

Summary

- Local Allocation - spill code
- Global Allocation based on graph colouring
- Techniques to reduce spill code
