#### Elements of Programming Languages

Lecture 12: Imperative programming

James Cheney

University of Edinburgh

October 31, 2024

#### The story so far

- So far we've mostly considered *pure* computations.
- Once a variable is bound to a value, the value never changes.
  - that is, variables are immutable.
- This is **not** how most programming languages treat variables!
  - In most languages, we can assign new values to variables: that is, variables are mutable by default
- Just a few languages are completely "pure" (Haskell).
- Others strike a balance:
  - e.g. Scala distinguishes immutable (val) variables and mutable (var) variables
  - similarly const in Java, C

#### Mutable vs. immutable

- Advantages of immutability:
  - Referential transparency (substitution of equals for equals); programs easier to reason about and optimize
  - Types tell us more about what a program can/cannot do
- Advantages of mutability:
  - Some common data structures easier to implement
  - Easier to translate to machine code (in a performance-preserving way)
  - Seems closely tied to popular OOP model of "objects with hidden (mutable) state and public methods"
- ullet Today we'll consider programming with assignable variables and loops ( $L_{While}$ ) and then discuss procedures and other forms of control flow

#### While-programs

• Let's start with a simple example: L<sub>While</sub>, with statements

```
Stmt \ni s ::= skip \mid s_1; s_2 \mid x := e
\mid if e then s_1 else s_2 \mid while e do s
```

- skip does nothing
- $s_1$ ;  $s_2$  does  $s_1$ , then  $s_2$
- x := e evaluates e and **assigns** the value to x
- if e then  $s_1$  else  $s_2$  evaluates e, and evaluates  $s_1$  or  $s_2$  based on the result.
- while *e* do *s* tests *e*. If true, evaluate *s* and **loop**; otherwise stop.
- We typically use {} to parenthesize statements.

### A simple example: factorial again

In Scala, mutable variables can be defined with var

```
var n = ...
var x = 1
while(n > 0) {
   x = n * x
   n = n-1
}
```

• In L<sub>While</sub>, all variables are mutable

```
x := 1; while (n > 0) do \{x := n * x; n := n - 1\}
```

#### An interpreter for L<sub>While</sub>

#### We will define a *pure* interpreter:

```
def exec(env: Env[Value], s: Stmt): Env[Value] =
s match {
 case Skip => env
 case Seq(s1,s2) =>
   val env1 = exec(env, s1)
   exec(env1.s2)
 case IfThenElseS(e,s1,s2) => eval(env,e) match {
   case BoolV(true) => exec(env.s1)
   case BoolV(false) => exec(env,s2)
```

## An interpreter for L<sub>While</sub>

```
def exec(env: Env[Value], s: Stmt): Env[Value] =
s match {
  . . .
 case WhileDo(e,s) => eval(env, e) match {
   case BoolV(true) =>
     val env1 = exec(env.s)
     exec(env1, WhileDo(e,s))
   case BoolV(false) => env
 }
 case Assign(x,e) =>
   val v = eval(env,e)
   env + (x \rightarrow v)
```

#### While-programs: evaluation

#### $\sigma, s \Downarrow \sigma'$

$$\frac{\sigma, s_1 \Downarrow \sigma' \quad \sigma', s_2 \Downarrow \sigma''}{\sigma, s_1; s_2 \Downarrow \sigma''}$$

$$\frac{\sigma, e \Downarrow \text{true} \quad \sigma, s_1 \Downarrow \sigma'}{\sigma, \text{if } e \text{ then } s_1 \text{ else } s_2 \Downarrow \sigma'} \quad \frac{\sigma, e \Downarrow \text{ false} \quad \sigma, s_2 \Downarrow \sigma'}{\sigma, \text{if } e \text{ then } s_1 \text{ else } s_2 \Downarrow \sigma'}$$

$$\frac{\sigma, e \Downarrow \text{ true} \quad \sigma, s \Downarrow \sigma' \quad \sigma', \text{ while } e \text{ do } s \Downarrow \sigma''}{\sigma, \text{ while } e \text{ do } s \Downarrow \sigma''}$$

$$\frac{\sigma, e \Downarrow \text{ false}}{\sigma, \text{ while } e \text{ do } s \Downarrow \sigma'} \quad \frac{\sigma, e \Downarrow \nu}{\sigma, x := e \Downarrow \sigma[x := \nu]}$$

• Here, we use evaluation in context  $\sigma$ ,  $e \Downarrow v$  (cf. Assignment 2)

#### Examples

• x := y + 1; z := 2 \* x

$$\frac{\sigma_1, y + 1 \Downarrow 2}{\sigma_1, x := y + 1 \Downarrow \sigma_2} \quad \frac{\sigma_2, 2 * x \Downarrow 4}{\sigma_2, z := 2 * x \Downarrow \sigma_3}$$
$$\sigma_1, x := y + 1; z := 2 * x \Downarrow \sigma_3$$

where

$$\sigma_1 = [y := 1]$$
 $\sigma_2 = [x := 2, y := 1]$ 
 $\sigma_3 = [x := 2, y := 1, z := 4]$ 

#### Other control flow constructs

- We've taken "if" (with both "then" and "else" branches) and "while" to be primitive
- We can **define** some other operations in terms of these:

• as seen in C, Java, etc.

#### **Procedures**

- L<sub>While</sub> is not a realistic language.
- Among other things, it lacks procedures

```
Example (C/Java):
  int fact(int n) {
    int x = 1;
    while (n > 0) {
      x = x*n:
      n = n-1;
    return x;
```

- Procedures can be added to L<sub>While</sub> (much like functions in  $L_{Rec}$ )
- Rather than do this, we'll show how to combine L<sub>While</sub> with  $L_{Rec}$  later.

# Structured vs. unstructured programming [Non-examinable]

- All of the languages we've seen so far are structured
  - meaning, control flow is managed using if, while, procedures, functions, etc.
- However, low-level machine code doesn't have any of these.
- A machine-code program is just a sequence of instructions in memory
- The only control flow is branching:
  - "unconditionally go to instruction at address n"
  - "if some condition holds, go to instruction at address n"
- Similarly, "goto" statements were the main form of control flow in many early languages

# "GO TO" Considered Harmful [Non-examinable]

- In a famous letter (CACM 1968), Dijkstra listed many disadvantages of "goto" and related constructs
- It allows you to write "spaghetti code", where control flow is very difficult to decipher
- For efficiency/historical reasons, many languages include such "unstructured" features:
  - "goto" jump to a specific program location
  - "switch" statements
  - "break" and "continue" in loops
- It's important to know about these features, their pitfalls and their safe uses

# goto in C [Non-examinable]

- The C (and C++) language includes goto
- In C, goto L jumps to the statement labeled L
- A typical (relatively sane) use of goto

```
... do some stuff ...
  if (error) goto error;
... do some more stuff ...
  if (error2) goto error;
... do some more stuff...
error: .. handle the error...
```

 We'll see other, better-structured ways to do this using exceptions.

# goto in C: pitfalls [Non-examinable]

- The scope of the goto L statement and the target L might be different
- for that matter, they might not even be in the same procedure!
- For example, what does this do:

```
goto L;
if(1) {
    int k = fact(3);
L: printf("%d",k);
}
```

Answer: k will be some random value!

# goto: caveats [Non-examinable]

- goto can be used safely in C, but is best avoided unless you have a really good reason
- e.g. very high performance/systems code
- Safe use: within same procedure/scope
- Or: to jump "out" of a nested loop

# goto fail [Non-examinable]

• What's wrong with this picture?

```
if (error test 1)
  goto fail;
if (error test 2)
  goto fail;
  goto fail;
if (error test 3)
  goto fail;
...
fail: ... handle error ...
```

- (In C, braces on if are optional; if they're left out, only the first goto fail statement is conditional!)
- This led to an Apple SSL security vulnerability in 2014 (see https://gotofail.com/)

## switch statements [Non-examinable]

- We've seen case or match constructs in Scala
- The switch statement in C, Java, etc. is similar:

```
switch (month) {
  case 1: print("January"); break;
  case 2: print("February"); break;
  ...
  default: print("unknown month"); break;
}
```

- However, typically the argument must be a base type like int
- (but see Java 21's new *pattern matching for switch* extension https://openjdk.org/jeps/441)

## switch statements: gotchas [Non-examinable]

- See the break; statement?
- It's an important part of the control flow!
  - it says "now jump out the end of the switch statement"

```
month = 1;
switch (month) {
  case 1: print("January");
  case 2: print("February");
  ...
  default: print("unknown month");
} // prints all months!
```

 Can you think of a good reason why you would want to leave out the break?

# Break and continue [Non-examinable]

 The break and continue statements are also allowed in loops in C/Java family languages.

```
for(i = 0; i < 10; i++) {
  if (i % 2 == 0) continue;
  if (i == 7) break;
  print(i);
}</pre>
```

- "Continue" says Skip the rest of this iteration of the loop.
- "Break" says Jump to the next statement after this loop

# Break and continue [Non-examinable]

 The break and continue statements are also allowed in loops in C/Java family languages.

```
for(i = 0; i < 10; i++) {
  if (i % 2 == 0) continue;
  if (i == 7) break;
  print(i);
}</pre>
```

- "Continue" says Skip the rest of this iteration of the loop.
- "Break" says Jump to the next statement after this loop
- This will print 135 and then exit the loop.

# Labeled break and continue [Non-examinable]

• In Java, break and continue can use labels.

```
OUTER: for(i = 0; i < 10; i++) {
    INNER: for(j = 0; j < 10; j++) {
        if (j > i) continue INNER;
        if (i == 4) break OUTER;
        print(j);
    }
}
```

• This will print 0010120123 and then exit the loop.

# Labeled break and continue [Non-examinable]

In Java, break and continue can use labels.

```
OUTER: for(i = 0; i < 10; i++) {
    INNER: for(j = 0; j < 10; j++) {
        if (j > i) continue INNER;
        if (i == 4) break OUTER;
        print(j);
    }
}
```

- This will print 0010120123 and then exit the loop.
- (Labeled) break and continue accommodate some of the safe uses of goto without as many sharp edges

#### Summary

- Many real-world programming languages have:
  - mutable state
  - structured control flow (if/then, while, exceptions)
  - procedures
- We've showed how to model and interpret L<sub>While</sub>, a simple imperative language
- and discussed a variety of (unstructured) control flow structures, such as "goto", "switch" and "break/continue".
- Next time:
  - Small-step semantics and type soundness
