## Tutorial 5: Modules and Objects

### Week 7 (October 28–November 1, 2024)

Exercises marked  $\star$  are more advanced. Please try all unstarred exercises before the tutorial meeting.

#### 1. Typing derivations

Construct typing derivations for the following expressions, or argue why they are not well-formed:

- (a)  $\Lambda A. \lambda x:A. x + 1$
- (b)  $(\star) \Lambda A. \lambda x:A \times A. \text{if } \text{fst } x == \text{snd } x \text{ then } \text{fst } x \text{ else } \text{snd } x$  (and how does its well-formedness depend on the typing rule for equality?)

#### 2. Evaluation derivations

Construct evaluation derivations for the following expressions, or explain why they do not evaluate:

- (a)  $(\Lambda A. \lambda x:A. x + 1)[\text{int}] 42$
- (b)  $(\Lambda A. \lambda x:A. x + 1)[\text{bool}] \text{true}$

#### 3. $(\star)$ Lists and polymorphism

Recall the proposed rules for lists from the previous tutorial.

$$\begin{aligned}
 e & ::= \dots \mid \text{nil} \mid e_1 :: e_2 \mid \text{case}_{\text{list}} e \text{ of } \{\text{nil} \Rightarrow e_1 ; x :: y \Rightarrow e_2\} \\
 v & ::= \dots \mid \text{nil} \mid v_1 :: v_2 \\
 \tau & ::= \dots \mid \text{list}[\tau]
 \end{aligned}$$

Define  $L_{\text{List}}$  to be  $L_{\text{Poly}}$  extended with the above constructs.

- (a) Write a polymorphic function  $\text{map}$  that has this type:

$$\forall A. \forall B. (A \rightarrow B) \rightarrow (\text{list}[A] \rightarrow \text{list}[B])$$

so that  $\text{map}(f)(l)$  is the function that traverses a list of  $A$ 's and, for each element  $x$  in  $l$ , applies the function  $f$  to it.

- (b) Write out a typing derivation tree for the expression

$$\text{map}[\text{int}][\text{int}](\lambda x. x + 1)(2 :: \text{nil})$$

assuming that  $\text{map}$  has the type given above.

- (c) Are lists and their associated operations definable in  $L_{\text{Poly}}$  already? Why or why not?

#### 4. Modules and Interfaces in Scala

Consider the following Scala object definition.

---

```
object A {
  type T = Int
  val c: T = 1
  val d: T = 2
  def f(x: T, y:T): T = x + y
}
object B {
  type T = String
  val c: T = "abcd"
  val d: T = "1234"
  def f(x: T, y: T) = x + y
}
```

---

- (a) Write expressions showing how to access each of the elements of `A` and `B`.
- (b) Suppose we execute the import statements

---

```
import A._
import B._
```

---

after finishing the declaration of `A`. What does unqualified identifier `d` refer to after that? What if we import in the opposite order?

- (c) (\*) Construct a Scala trait `ABlike` defining bindings for all of the components of `A` and `B`, and so that we can assert that both `A` and `B` extend `ABlike`.
- (d) (\*) Define a function `g` taking an argument `x: ABlike` that applies `f` to `c` and `d`. Apply it to both instances of `ABlike` above. What is its return type?
- (e) (\*) Create an anonymous instance of `ABlike` with `T = Boolean` and call the function `g` on it.

#### 5. (\*) Ad hoc polymorphism

Traits can also accommodate overloading and reuse of the same name for operations on different types. An operation such as `size` can be defined as part of a trait as follows:

---

```
trait HasSize { def size(): Int }
```

---

- (a) Modify the definition of `List[A]` above so that it extends `HasSize`, and define an appropriate `size` method for it.
- (b) Modify the definition of `Tree[A]` so that it extends `HasSize` and define its `size` operation.
- (c) Write a function `sameSize` that takes two values of type `HasSize` and checks whether they have the same size.
- (d) Call this function on a `List[Int]` and a `Tree[String]` to verify that the correct implementations of `size` are called for different types.
