Part-of-speech Tagging and HMMs

Ivan Titov

(with slides by Alex Lascarides, Sharon Goldwater & Philipp Koehn)

What is part of speech tagging?

- Given a string:

This is a simple sentence

- Identify parts of speech (syntactic categories):

This/DET is/VB a/DET simple/ADJ sentence/NOUN

Why do we care about POS tagging?

- POS tagging is a first step towards syntactic analysis (which in turn, is in turn a fundamental linguistic task).
 - traditionally, POS tags were found to be useful in NLP tasks
- Linguistic representations (including PoS) play around in models of human language processing / psycholinguistics
- Illustrates the use of **hidden Markov models** (HMMs), which are also used for many other tagging (sequence labelling) tasks.
- The Viterbi algorithm, which we will introduce for POS tagging with HMMs, and its extensions are used in many other applications in language processing and beyond

Examples of other tagging tasks

- **Named entity recognition:** e.g., label words as belonging to **persons**, **organizations**, **locations**, or none of the above:

Barack/PER Obama/PER spoke/NON from/NON the/NON White/LOC
House/LOC today/NON ./NON

- **Information field segmentation:** Given specific type of text (classified advert, bibliography entry), identify which words belong to which “fields” (price/size/location, author/title/year)

3BR/SIZE flat/TYPE in/NON Bruntsfield/LOC ,/NON near/LOC
main/LOC roads/LOC ./NON Bright/FEAT ,/NON well/FEAT maintained/FEAT
...

Sequence labelling: key features

In all of these tasks, deciding the correct label depends on

- the word to be labeled
 - NER: **Smith** is probably a person.
 - POS tagging: **chair** is probably a noun.
- the labels of surrounding words
 - NER: if following word is an organization (say **Corp.**), then this word is more likely to be organization too.
 - POS tagging: if preceding word is a modal verb (say **will**) then this word is more likely to be a verb.

HMM combines these sources of information probabilistically.

Parts of Speech: reminder

- **Open class words** (or content words)
 - nouns, verbs, adjectives, adverbs
 - mostly content-bearing: they refer to objects, actions, and features in the world
 - *open* class, since there is no limit to what these words are, new ones are added all the time ([email](#), [website](#)).
- **Closed class words** (or function words)
 - pronouns, determiners, prepositions, connectives, ...
 - there is a limited number of these
 - mostly functional: to tie the concepts of a sentence together

How many parts of speech?

- Both linguistic and practical considerations
- Corpus annotators decide. Distinguish between
 - proper nouns (names) and common nouns?
 - singular and plural nouns?
 - past and present tense verbs?
 - auxiliary and main verbs?
 - etc
- Commonly used tagsets for English usually have 40-100 tags. For example, the Penn Treebank has 45 tags.

Tag	Description	Example	Tag	Description	Example
CC	coordin. conjunction	<i>and, but, or</i>	SYM	symbol	<i>+, %, &</i>
CD	cardinal number	<i>one, two</i>	TO	“to”	<i>to</i>
DT	determiner	<i>a, the</i>	UH	interjection	<i>ah, oops</i>
EX	existential ‘there’	<i>there</i>	VB	verb base form	<i>eat</i>
FW	foreign word	<i>mea culpa</i>	VBD	verb past tense	<i>ate</i>
IN	preposition/sub-conj	<i>of, in, by</i>	VBG	verb gerund	<i>eating</i>
JJ	adjective	<i>yellow</i>	VBN	verb past participle	<i>eaten</i>
JJR	adj., comparative	<i>bigger</i>	VBP	verb non-3sg pres	<i>eat</i>
JJS	adj., superlative	<i>wildest</i>	VBZ	verb 3sg pres	<i>eats</i>
LS	list item marker	<i>1, 2, One</i>	WDT	wh-determiner	<i>which, that</i>
MD	modal	<i>can, should</i>	WP	wh-pronoun	<i>what, who</i>
NN	noun, sing. or mass	<i>llama</i>	WP\$	possessive wh-	<i>whose</i>
NNS	noun, plural	<i>llamas</i>	WRB	wh-adverb	<i>how, where</i>
NNP	proper noun, sing.	<i>IBM</i>	\$	dollar sign	<i>\$</i>
NNPS	proper noun, plural	<i>Carolinas</i>	#	pound sign	<i>#</i>
PDT	predeterminer	<i>all, both</i>	“	left quote	<i>‘ or “</i>
POS	possessive ending	<i>’s</i>	”	right quote	<i>’ or ”</i>
PRP	personal pronoun	<i>I, you, he</i>	(left parenthesis	<i>[, (, {, <</i>
PRP\$	possessive pronoun	<i>your, one’s</i>)	right parenthesis	<i>],), }, ></i>
RB	adverb	<i>quickly, never</i>	,	comma	<i>,</i>
RBR	adverb, comparative	<i>faster</i>	.	sentence-final punc	<i>. ! ?</i>
RBS	adverb, superlative	<i>fastest</i>	:	mid-sentence punc	<i>: ; ... --</i>
RP	particle	<i>up, off</i>			

J&M Fig 5.6: Penn Treebank POS tags

POS tags in other languages

- Morphologically rich languages often have compound morphosyntactic tags

Noun+A3sg+P2sg+Nom (J&M3, Chapter 10.7)

- Hundreds or thousands of possible combinations
- Predicting these requires more complex methods than what we will discuss (e.g., may combine an FST with a probabilistic disambiguation system)

Why is POS tagging hard?

The usual reasons!

- Ambiguity:

glass of water/NOUN	vs.	water/VERB the plants
lie/VERB down	vs.	tell a lie/NOUN
wind/VERB down	vs.	a mighty wind/NOUN

How about time flies like an arrow?

- Sparse data:

- Words we haven't seen before (at all, or in this context)
- Word-Tag pairs we haven't seen before (e.g., if we verb a noun)

Relevant knowledge for POS tagging

Remember, we want a model that decides tags based on

- The word itself
 - Some words may only be nouns, e.g. *arrow*
 - Some words are ambiguous, e.g. *like*, *flies*
 - Probabilities may help, if one tag is more likely than another
- Tags of surrounding words
 - two determiners rarely follow each other
 - two base form verbs rarely follow each other
 - determiner is almost always followed by adjective or noun

A probabilistic model for tagging

To incorporate these sources of information, we imagine that the sentences we observe were generated probabilistically as follows.

- To generate sentence of length n :

Let $y_0 = \langle s \rangle$

For $i = 1$ to n

Choose a tag conditioned on previous tag: $P(y_i | y_{i-1})$

Choose a word conditioned on its tag: $P(x_i | y_i)$

- So, the model assumes:
 - Each tag depends only on previous tag: a bigram tag model.
 - Words are independent given tags

Probabilistic finite-state machine

- One way to view the model: sentences are generated by walking through **states** in a graph. Each state represents a tag.

- Prob of moving from state s to s' (**transition probability**): $P(y_i = s' | y_{i-1} = s)$

Example transition probabilities

$t_{i-1} \backslash t_i$	NNP	MD	VB	JJ	NN	...
<s>	0.2767	0.0006	0.0031	0.0453	0.0449	...
NNP	0.3777	0.0110	0.0009	0.0084	0.0584	...
MD	0.0008	0.0002	0.7968	0.0005	0.0008	...
VB	0.0322	0.0005	0.0050	0.0837	0.0615	...
JJ	0.0306	0.0004	0.0001	0.0733	0.4509	...
...

- Probabilities estimated from tagged WSJ corpus, showing, e.g.:
 - Proper nouns (NNP) often begin sentences: $P(\text{NNP}|\text{<s>}) \approx 0.28$
 - Modal verbs (MD) nearly always followed by bare verbs (VB).
 - Adjectives (JJ) are often followed by nouns (NN).

From JM

Example transition probabilities

$t_{i-1} \backslash t_i$	NNP	MD	VB	JJ	NN	...
<s>	0.2767	0.0006	0.0031	0.0453	0.0449	...
NNP	0.3777	0.0110	0.0009	0.0084	0.0584	...
MD	0.0008	0.0002	0.7968	0.0005	0.0008	...
VB	0.0322	0.0005	0.0050	0.0837	0.0615	...
JJ	0.0306	0.0004	0.0001	0.0733	0.4509	...
...

- This table is incomplete!
- In the full table, every row must sum up to 1 because it is a **distribution** over the next state (given previous).

Table excerpted from J&M draft 3rd edition, Fig 8.5

Probabilistic finite-state machine: outputs

- When passing through each state, emit a word.

- Prob of emitting word x from state s (**emission** or **output probability**):
 $P(x_i = x | y_i = s)$

Example output probabilities

$y_i \backslash x_i$	Janet	will	back	the	...
NNP	0.000032	0	0	0.000048	...
MD	0	0.308431	0	0	...
VB	0	0.000028	0.000672	0	...
DT	0	0	0	0.506099	...
...

- MLE probabilities from tagged WSJ corpus, showing, e.g.:
 - 0.0032% of proper nouns are *Janet*: $P(\text{Janet}|\text{NNP}) = 0.000032$
 - About half of determiners (DT) are *the*.
 - *the* can also be a proper noun. (Annotation error?)
- Again, in full table, rows would sum to 1.

From J&M draft 3rd edition, Fig 8.6

What can we do with this model?

- If we know the transition and output probabilities, we can compute the probability of a tagged sentence.
- That is,
 - suppose we have sentence $X = x_1 \dots x_n$ and its tags $Y = y_1 \dots y_n$.
 - what is the probability that our probabilistic FSM would generate exactly that sequence of words and tags, if we stepped through at random?

What can we do with this model?

- If we know the transition and output probabilities, we can compute the probability of a tagged sentence.
- That is,
 - suppose we have sentence $X = x_1 \dots x_n$ and its tags $Y = y_1 \dots y_n$.
 - what is the probability that our probabilistic FSM would generate exactly that sequence of words and tags, if we stepped through at random?
- This is the **joint probability** $P(Y, X) = \prod_{i=1}^n P(y_i | y_{i-1}) P(x_i | y_i)$

Example: computing joint prob. $P(X, Y)$

What's the probability of this tagged sentence?

This/DET is/VB a/DET simple/JJ sentence/NN

Example: computing joint prob. $P(X, Y)$

What's the probability of this tagged sentence?

This/DET is/VB a/DET simple/JJ sentence/NN

- First, add begin- and end-of-sentence $\langle s \rangle$ and $\langle /s \rangle$. Then:

$$\begin{aligned} p(X, Y) &= \prod_{i=1}^n P(y_i | y_{i-1}) P(x_i | y_i) \\ &= P(\text{DET} | \langle s \rangle) P(\text{VB} | \text{DET}) P(\text{DET} | \text{VB}) P(\text{JJ} | \text{DET}) P(\text{NN} | \text{JJ}) P(\langle /s \rangle | \text{NN}) \\ &\quad \cdot P(\text{This} | \text{DET}) P(\text{is} | \text{VB}) P(\text{a} | \text{DET}) P(\text{simple} | \text{JJ}) P(\text{sentence} | \text{NN}) \end{aligned}$$

- Then, plug in the probabilities we estimated from our corpus.

But... tagging?

Normally, we want to use the model to find the best tag sequence for an *untagged* sentence.

- Thus, the name of the model: **hidden Markov model**
 - **Markov**: because of Markov independence assumption (each tag/state only depends on fixed number of previous tags/states—here, just one).
 - **hidden**: because at test time we only see the words/emissions; the tags/states are hidden (or **latent**) variables.
- FSM view: given a sequence of words, what is the most probable state path that generated them?

Hidden Markov Model (HMM)

HMM is actually a very general model for sequences. Elements of an HMM:

- a set of states (here: the tags)
- a set of output symbols (here: words)
- initial state (here: beginning of sentence)
- state transition probabilities (here: $p(y_i|y_{i-1})$)
- symbol emission probabilities (here: $p(x_i|y_i)$)

Relationship to previous models

- **N-gram model:** a model for sequences that also makes a Markov assumption, but has no hidden variables.
- **Naive Bayes:** a model with hidden variables (the classes) but no sequential dependencies.
- **HMM:** a model for sequences with hidden variables.

Like many other models with hidden variables, we will use Bayes' Rule to help us infer the values of those variables.

We usually assume hidden variables *are* observed during training—annotated data

Formalizing the tagging problem

Find the best tag sequence Y for an *untagged* sentence X :

$$\operatorname{argmax}_Y p(Y|X)$$

Formalizing the tagging problem

Find the best tag sequence Y for an *untagged* sentence X :

$$\operatorname{argmax}_Y p(Y|X)$$

- Bayes' rule gives us:

$$p(Y|X) = \frac{p(X|Y) p(Y)}{p(X)}$$

- We can drop $p(X)$ if we are only interested in argmax_T :

$$\operatorname{argmax}_Y p(Y|X) = \operatorname{argmax}_Y p(X|Y) p(Y)$$

Decomposing the model

Now we need to compute $P(X|Y)$ and $P(Y)$ (actually, their product $P(X|Y)P(Y) = P(X, Y)$).

- We already defined how!
- $P(T)$ is the state transition sequence:

$$P(Y) = \prod_i P(y_i | y_{i-1})$$

- $P(X|Y)$ are the emission probabilities:

$$P(X|Y) = \prod_i P(x_i | y_i)$$

Search for the best tag sequence

- We have defined a model, but how do we use it?
 - given: word sequence X
 - wanted: best tag sequence Y^*
- For any specific tag sequence Y , it is easy to compute $P(X, Y) = P(X|Y)P(Y)$.

$$P(X|Y) P(Y) = \prod_i P(x_i|y_i) P(y_i|y_{i-1})$$

- So, can't we just enumerate all possible Y , compute their probabilities, and choose the best one?

Enumeration won't work

- Suppose we have c possible tags for each of the n words in the sentence.
- How many possible tag sequences?

Enumeration won't work

- Suppose we have c possible tags for each of the n words in the sentence.
- How many possible tag sequences?
- There are c^n possible tag sequences: the number grows *exponentially* in the length n .
- For all but small n , too many sequences to efficiently enumerate.
- We could also use beam search to do approximate search

The Viterbi algorithm

- We'll use a **dynamic programming** algorithm to solve the problem.
- The **Viterbi algorithm** finds the best tag sequence without explicitly enumerating all sequences.
- The algorithm stores partial results in a **chart** to avoid recomputing them.
- Exact, unlike beam search (or greedy, or sampling)
- Details next time.

Summary

- Part-of-speech tagging is a sequence labelling task.
- HMM uses two sources of information to help resolve ambiguity in a word's POS tag:
 - The words itself
 - The tags assigned to surrounding words
- Can be viewed as a probabilistic FSM.
- Given a tagged sentence, easy to compute its probability. But finding the best tag sequence will need a clever algorithm.
- Next time, we will also discuss how we can combine this ideas with neural networks
