

Inf1B

Creating Classes

Perdita Stevens

adapting earlier versions by Ewan Klein, Volker Seeker, et al.

School of Informatics

Creating classes

Last time we saw how to use a class:

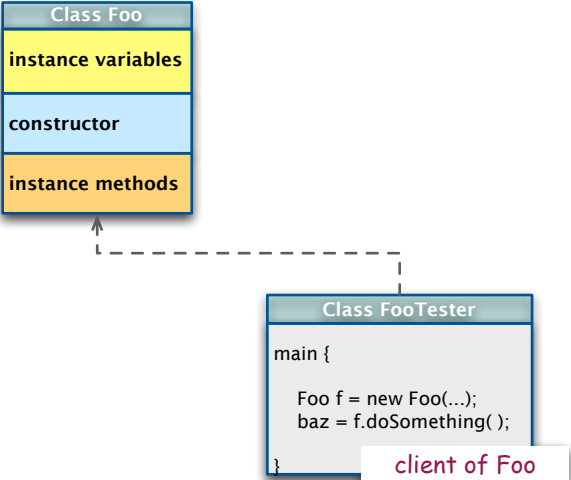

- ▶ create a new object, using `new`;
- ▶ send the object messages from its interface, to invoke its behaviour;
- ▶ we understood that the object might change its state;
- ▶ and that state and behaviour interdepend;
- ▶ but we did not expect to have access to the state, and we did not know **or need to care** exactly how the behaviour was implemented.

This time we will see how to define a class, including its state and behaviour, and how new objects should be created.

Classes and Clients

Classes and Clients

Classes and Clients

Client code:

- ▶ In general, a **client** program calls a method of some class **C**.
- ▶ Example: class **FooTester** is a client of **Foo** because it calls the **doSomething()** instance method on **Foo** objects.

Classes and Clients

Client code:

- ▶ In general, a **client** program calls a method of some class **C**.
- ▶ Example: class **FooTester** is a client of **Foo** because it calls the **doSomething()** instance method on **Foo** objects.

Test-first design methodology:

1. Think about the methods a client would call on instances of class **C**.
2. Design the API for class **C**.
3. Implement a client **CTester** for **C** which tests the desired behaviour.
4. Implement **C** so that it satisfies **CTester**.

CircleTester

- ▶ Create a Circle object `c1`.
- ▶ Call a method to get the area of that object: `c1.getArea()`

```
public class CircleTester {  
  
    public static void main(String[] args) {  
        Circle c1 = new Circle();  
        double area1 = c1.getArea();  
        System.out.printf("Area of circle c1 is %5.2f\n", area1);  
  
        Circle c2 = new Circle(5.0);  
        double area2 = c2.getArea();  
        System.out.printf("Area of circle c2 is %5.2f\n", area2);  
    }  
}
```

Expected Output

```
% java CircleTester  
Area of circle c1 is  3.14  
Area of circle c2 is 78.54
```

The Circle Class

The Circle Class: Instance Methods

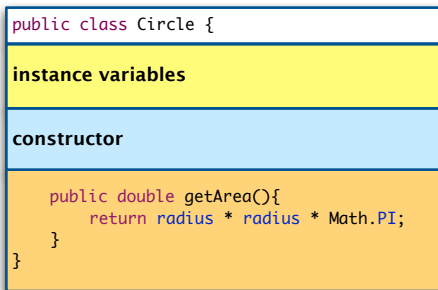

```
public class Circle {
```

instance variables

constructor

```
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

The Circle Class: Instance Methods

- ▶ `getArea()` is an instance method of the class `Circle`.
- ▶ How does it know about `radius`?

The Circle Class: Instance Variables

```
public class Circle {  
    private double radius;  
  
    constructor  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

- ▶ `radius` is an instance variable of the class `Circle`.

The Circle Class: Instance Variables

```
public class Circle {  
    private double radius;  
  
    constructor  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

- ▶ `radius` is an instance variable of the class `Circle`.
- ▶ Instance variables are declared **outside** methods and have scope over the whole class.

The Circle Class: Instance Variables

```
public class Circle {  
    private double radius;  
  
    constructor  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

- ▶ `radius` is an instance variable of the class `Circle`.
- ▶ Instance variables are declared **outside** methods and have scope over the whole class.
- ▶ An instance method of a class can use any instance variable of that class.

The Circle Class: Instance Variables

```
public class Circle {  
    private double radius;  
  
    constructor  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

- ▶ `radius` is an instance variable of the class `Circle`.
- ▶ Instance variables are declared **outside** methods and have scope over the whole class.
- ▶ An instance method of a class can use any instance variable of that class.
- ▶ Instance variables do **not** have to be initialised; they get default values (e.g., 0 for `int`, `false` for `boolean`, `null` for all reference types).

The Circle Class: Instance Variables

```
public class Circle {  
    private double radius;  
  
    constructor  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

- ▶ `radius` is an instance variable of the class `Circle`.
- ▶ Instance variables are declared **outside** methods and have scope over the whole class.
- ▶ An instance method of a class can use any instance variable of that class.
- ▶ Instance variables do **not** have to be initialised; they get default values (e.g., 0 for `int`, `false` for `boolean`, `null` for all reference types).
- ▶ How does a `Circle` object's radius get set?

The Circle Class: Constructors

```
public class Circle {  
    private double radius;  
  
    public Circle(double newRadius){  
        radius = newRadius;  
    }  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

Constructor

- ▶ has same name as the class;

The Circle Class: Constructors

```
public class Circle {  
    private double radius;  
  
    public Circle(double newRadius){  
        radius = newRadius;  
    }  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

Constructor

- ▶ has same name as the class;
- ▶ used to initialise an object that has been created: `new Circle(5.0);`

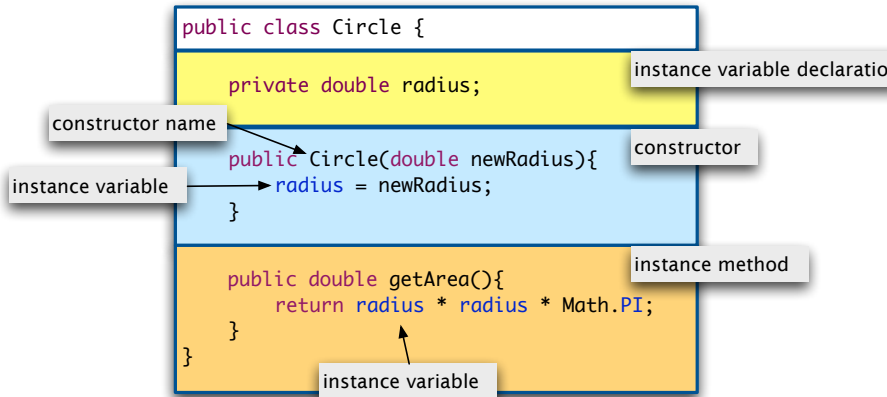

The Circle Class: Constructors

```
public class Circle {  
    private double radius;  
  
    public Circle(double newRadius){  
        radius = newRadius;  
    }  
  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

Constructor

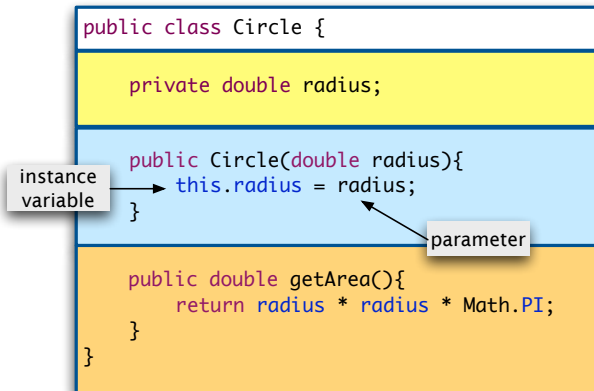

- ▶ has same name as the class;
- ▶ used to initialise an object that has been created: `new Circle(5.0);`
- ▶ must **not** have a return type (not even `void`).

The Circle Class: Anatomy

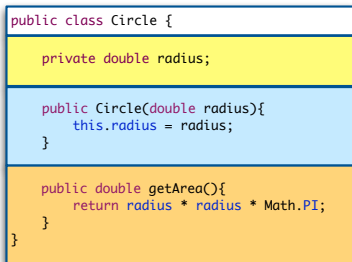

The Circle Class: Constructors

Alternative notation:

The Circle Class: Client

client of Circle

Interim Summary

We looked at:

- ▶ using client programs to motivate our classes, and to test them
- ▶ **instance variables**:
 - ▶ represent data that is particular to an object (i.e., an instance!);
 - ▶ have scope over the whole class;
 - ▶ can hold mutable state;
 - ▶ can be manipulated by any instance method in the class.
- ▶ **instance methods**:
 - ▶ like static methods, but can only be called on some object `o`;
 - ▶ have access to the data that is specific to `o`.
- ▶ **constructors**:
 - ▶ we create a new object of class `Foo` with the keyword `new`;
 - ▶ we initialise an object of type `Foo` by calling the constructor for that type;
 - ▶ the constructor is used to store data values in the object's instance variables.

Let's practise that

<https://www.theodysseyonline.com/your-brain-is-muscle-exercise-it>

What does it print?

```
public class Number {
    public int x;
    public Number() { }
}

public class Main {
    public static void main(String[] args) {
        Number a = new Number();
        System.out.println(a.x);
        a.x = 4;
        System.out.println(a.x);
        Number b = a;
        b.x = 5;
        System.out.println(a.x);
    }
}
```

What does it print?

```
public class Number {
    public int x;
    public Number() { }
}

public class Main {
    public static void main(String[] args) {
        Number a = new Number();
        System.out.println(a.x);
        a.x = 4;
        System.out.println(a.x);
        Number b = a;
        b.x = 5;
        System.out.println(a.x);
    }
}
```

Prints **0 4 5** because default initialisation of int and copying reference rather than object.

What does it print?

```
public class Operation{
    public int data;
    public Operation(int d) {
        data = d;
    }
    public void change(int d){
        data = d + 100;
    }
}

public class Main {
    public static void main(String[] args){
        Operation op = new Operation(50);
        System.out.println("before_change" + op.data);
        op.change(500);
        System.out.println("after_change" + op.data);
    }
}
```

What does it print?

```
public class Operation{
    public int data;
    public Operation(int d) {
        data = d;
    }
    public void change(int d){
        data = d + 100;
    }
}

public class Main {
    public static void main(String[] args){
        Operation op = new Operation(50);
        System.out.println("before_change" + op.data);
        op.change(500);
        System.out.println("after_change" + op.data);
    }
}
```

Prints **before change 50** - **after change 600** because old data value is replaced.

What does it print?

```
public class Person {
    public String name;
    public Person() { }
    public void assignName(String n) {
        if (name.length() == 0) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

What does it print?

```
public class Person {
    public String name;
    public Person() { }
    public void assignName(String n) {
        if (name.length() == 0) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

Runtime error **NullPointerException** because default value of name is **null**.

What does it print?

```
public class Person {
    public String name = "";
    public Person() { }
    public void assignName(String n) {
        if (name.length() == 0) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

What does it print?

```
public class Person {
    public String name = "";
    public Person() { }
    public void assignName(String n) {
        if (name.length() == 0) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

Prints **Lee** because initialised to empty String with declaration and then set in method.

What does it print?

```
public class Person {
    public String name;
    public Person() { }
    public void assignName(String n) {
        if (name.equals(null)) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

What does it print?

```
public class Person {
    public String name;
    public Person() { }
    public void assignName(String n) {
        if (name.equals(null)) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

Runtime error **NullPointerException**. Not even **.equals** can be called on **null**.

What does it print?

```
public class Person {
    public String name;
    public Person() { }
    public void assignName(String n) {
        if (name == null) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

What does it print?

```
public class Person {
    public String name;
    public Person() { }
    public void assignName(String n) {
        if (name == null) name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person();
        p.assignName("Lee");
        System.out.println(p.name);
    }
}
```

Prints **Lee** because == comparison works.

What does it print?

```
public class Person {
    public String name = "John_Doe";

    public Person(String n) {
        System.out.println(name);
        name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person("Lee");
        System.out.println(p.name);
    }
}
```

What does it print?

```
public class Person {
    public String name = "John_Doe";

    public Person(String n) {
        System.out.println(name);
        name = n;
    }
}

public class Main {
    public static void main(String[] args) {
        Person p = new Person("Lee");
        System.out.println(p.name);
    }
}
```

Prints **John Doe** - **Lee**. Initialisation with declaration is executed before the constructor body.

Let's look at a longer example.

Hotel Reservation System

Goal: create a data type to manage hotel bookings

- ▶ Each hotel room has a number and a room rate.
- ▶ Each hotel room is associated with a representation of the days of a single month, indicating which days the room has already been booked for.

Hotel Reservation System: Client

```
public class HotelRoomReserver {  
  
    public static void main(String[] args) {  
        int startDate = Integer.parseInt(args[0]);  
        int duration = Integer.parseInt(args[1]);  
  
        HotelRoom rm1 = new HotelRoom(1, 65);  
        HotelRoom rm2 = new HotelRoom(2, 65);  
        HotelRoom rm3 = new HotelRoom(3, 75);  
        HotelRoom[] rooms = { rm1, rm2, rm3 };  
  
        for (int i = 0; i < rooms.length; i++) {  
            HotelRoom r = rooms[i];  
            if (r.isAvailable(startDate, duration)) {  
                r.printBookings();  
            }  
        }  
    }  
}
```

Hotel Reservation System: Client

```
public class HotelRoomReserver {  
  
    public static void main(String[] args) {  
        int startDate = Integer.parseInt(args[0]);  
        int duration = Integer.parseInt(args[1]);  
  
        HotelRoom rm1 = new HotelRoom(1, 65);  
        HotelRoom rm2 = new HotelRoom(2, 65);  
        HotelRoom rm3 = new HotelRoom(3, 75);  
        HotelRoom[] rooms = { rm1, rm2, rm3 };  
  
        for (int i = 0; i < rooms.length; i++) {  
            HotelRoom r = rooms[i];  
            if (r.isAvailable(startDate, duration)) {  
                r.printBookings();  
            }  
        }  
    }  
}
```

create and
initialize
objects

invoke constructor

object name

invoke method on r

Hotel Room Data Type

Goal: create a data type to manage hotel bookings

Set of values:

type	value	remarks
int	room number	
int	room rate	expressed in £
boolean[]	booked dates	true at index i iff room is booked for day i

Hotel Room Data Type

Goal: create a data type to manage hotel bookings

API:

```
public class HotelRoom
```

```
    HotelRoom(int num, int rate)
```

```
    boolean isAvailable(int sd, int d)    available from day sd  
                                          until day sd + d?
```

```
    void printBookings()                show bookings for  
                                          whole month
```

```
    String toString()                   string representation
```

Assumptions:

- ▶ Simplify by only considering a single month;
- ▶ skip index 0 in the bookings so that indexes and days of month line up;
- ▶ if someone is booked from day i to day j , they depart from hotel on the morning of j , so room only has to be free on days $i - (j-1)$.

Arrays of Objects

Array of HotelRoom objects

```
HotelRoom rm1 = new HotelRoom(1, 65);  
HotelRoom rm2 = new HotelRoom(2, 65);  
HotelRoom rm3 = new HotelRoom(3, 75);  
HotelRoom[] rooms = { rm1, rm2, rm3 };
```

Array of HotelRoom objects: alternative

```
HotelRoom[] rooms = new HotelRoom[3];  
rooms[0] = new HotelRoom(1, 65);  
rooms[1] = new HotelRoom(2, 65);  
rooms[2] = new HotelRoom(3, 75);
```

- ▶ Allocate memory for the array with `new`.
- ▶ Allocate memory for each object with `new`.

HotelRoom Class, version 1

```
public class HotelRoom {
    private final int roomNumber;
    private int roomRate;

    public HotelRoom(int num, int rate){
        roomNumber = num;
        roomRate = rate;
    }

    public boolean isAvailable(int startDate, int duration){
        return true;
    }
}
```

More on Instance Variables

- ▶ Always use access modifier `private` (more on this later)
- ▶ Use modifier `final` for instance variables that never change after initial assignment.

Hotel Reservation System

Version 1

```
% java HotelReserver 12 3
Rooms available from 12 to 15
=====
HotelRoom@5f893efe
HotelRoom@2b86c6b2
HotelRoom@1d5ee671
```

Hotel Reservation System

Version 1

```
% java HotelReserver 12 3
Rooms available from 12 to 15
=====
HotelRoom@5f893efe
HotelRoom@2b86c6b2
HotelRoom@1d5ee671
```

How do we get a more informative output string when we call `System.out.println()` on a `HotelRoom` object?

Hotel Reservation System

Version 2

```
% java HotelReserver 12 3  
Rooms available from 12 to 15
```

```
=====
```

```
Room Number:    1  
Room Rate:      £65.00
```

```
Room Number:    2  
Room Rate:      £65.00
```

```
Room Number:    3  
Room Rate:      £75.00
```

HotelRoom Class, version 3

```
public class HotelRoom {
    private final int roomNumber;
    private int roomRate;
    private boolean[] booked;

    public HotelRoom(int num, int rate){
        roomNumber = num;
        roomRate = rate;
        booked = HotelUtils.occupy();
    }

    public boolean isAvailable(int startDate, int duration){
        boolean available = true;
        for (int i = startDate; i < startDate + duration; i++) {
            available = available && !booked[i];
        }
        return available;
    }

    public String toString(){
        return String.format("\nRoom Number:\t%s\nRoom Rate:\t£%.00",
                               roomNumber, roomRate);
    }
}
```

call an external utility
method which randomly
flips false to true.

HotelRoom Class, version 4

```
public class HotelRoom {
    private final int roomNumber;
    private int roomRate;
    private boolean[] booked;

    public HotelRoom(int num, int rate){
        roomNumber = num;
        roomRate = rate;
        booked = HotelUtils.occupy();
    }

    public boolean isAvailable(int startDate, int duration){
        boolean available = true;
        for (int i = startDate; i < startDate + duration; i++) {
            available = available && !booked[i];
        }
        return available;
    }

    public void printBookings(){
        HotelUtils.displayBookings(booked);
    }

    public String toString(){
        return String.format("\nRoom Number:\t%s\nRoom Rate:\t£%.00",
                               roomNumber, roomRate);
    }
}
```

another external utility method

Version 4

Version 4

```
% Rooms available from 12 to 15
```

```
=====
```

```
Room Number:      2
Room Rate:        £65.00
  1: [ ] [X] [ ] [X] [X] [X] [ ]
  8: [ ] [ ] [X] [ ] [ ] [ ] [ ]
 15: [X] [ ] [ ] [X] [ ] [ ] [ ]
 22: [X] [X] [X] [ ] [ ] [ ] [X]
 29: [X] [X]
```

Recall that guests will leave on morning of 15th, so room doesn't have to be free on day 15.

Interim Summary

Some new features:

- ▶ We implemented a `toString()` method for `HotelRoom`:
 - ▶ Java always implicitly calls this method whenever it executes commands like `System.out.println()`.
 - ▶ Every class gets a default version of `toString()`, but it's often useful to give our own classes a more specific implementation which gets used instead of the default.
- ▶ We created and used an array of type `HotelRoom[]`; i.e.

```
HotelRoom[] rooms = { rm1, rm2, rm3 };
```

More on Constructors

Circle1: Omitting the constructor

```
public class Circle1 {  
    private double radius;  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

More on Constructors

Circle1: Omitting the constructor

```
public class Circle1 {  
    private double radius;  
    public double getArea(){  
        return radius * radius * Math.PI;  
    }  
}
```

- ▶ `Circle1 c = new Circle1(1.0)` — causes compile-time error.
- ▶ `Circle1 c = new Circle1()` — **does** work
 - ▶ though `c.getArea()` returns 0.00!
- ▶ If you don't explicitly add a constructor, Java will automatically add a no-argument constructor for you.

More on Constructors

Circle again

```
public class Circle {
    private double radius;
    public Circle(double newRadius){
        radius = newRadius;
    }
    public double getArea(){
        return radius * radius * Math.PI;
    }
}
```

- ▶ What happens if we call `Circle c = new Circle();`?
- ▶ This also causes a compile-time error — we only get the no-arg default constructor **if there's no explicit constructor already defined.**

More on Constructors

Generally considered good programming style to provide a no-arg constructor for your classes but not always practical.

No-arg Constructor: Version 1

```
public class Circle3 {
    private double radius;
    public Circle3(double newRadius){
        radius = newRadius;
    }
    public Circle3(){
        radius = 1.0;
    }
    public double getArea(){
        return radius * radius * Math.PI;
    }
}
```

More on Constructors

No-arg Constructor: Version 2

```
public class Circle4 {
    private double radius;
    public Circle4(double newRadius){
        radius = newRadius;
    }
    public Circle4(){
        this(1.0);
    }
    public double getArea(){
        return radius * radius * Math.PI;
    }
}
```

- ▶ `this(1.0);` — call another constructor of this class, and supply the value 1.0.
- ▶ Must be the **first line** of the constructor.

Let's practise some more

<https://www.theodysseyonline.com/your-brain-is-muscle-exercise-it>

What does it print?

```
public class Operation{
    private int data;
    public Operation(int d) {
        data = d;
    }
    public void change(int data){
        data = data + 100;
    }
    public String toString() {
        return "" + data;
    }
}

public class Main {
    public static void main(String[] args){
        Operation op = new Operation(50);
        System.out.println("before_change_" + op.toString());
        op.change(500);
        System.out.println("after_change_" + op.toString());
    }
}
```

What does it print?

```
public class Operation{
    private int data;
    public Operation(int d) {
        data = d;
    }
    public void change(int data){
        data = data + 100;
    }
    public String toString() {
        return "" + data;
    }
}

public class Main {
    public static void main(String[] args){
        Operation op = new Operation(50);
        System.out.println("before_change_" + op.toString());
        op.change(500);
        System.out.println("after_change_" + op.toString());
    }
}
```

Prints **before change 50** - **after change 50** because change method modifies local field.

What does it print?

```
public class Operation{
    private int data;
    public Operation(int d) {
        data = d;
    }
    public void change(int data){
        this.data = data + 100;
    }
    public String toString() {
        return "" + data;
    }
}

public class Main {
    public static void main(String[] args){
        Operation op = new Operation(50);
        System.out.println("before_change_" + op.toString());
        op.change(500);
        System.out.println("after_change_" + op.toString());
    }
}
```

Prints **before change 50** - **after change 600** because change method modifies local field. Can be fixed with **this**.

What does it print?

```
public class Operation{
    private int data;
    public Operation(int d) {
        data = d;
    }
    public void change(Operation op){
        op.data = op.data + 100;
    }
    public String toString() {
        return data + "";
    }
}

public class Main {
    public static void main(String[] args){
        Operation op = new Operation(50);
        System.out.println("before_change_"+op);
        op.change(op);
        System.out.println("after_change_"+op);
    }
}
```

What does it print?

```
public class Operation{
    private int data;
    public Operation(int d) {
        data = d;
    }
    public void change(Operation op){
        op.data = op.data + 100;
    }
    public String toString() {
        return data + "";
    }
}

public class Main {
    public static void main(String[] args){
        Operation op = new Operation(50);
        System.out.println("before_change_"+op);
        op.change(op);
        System.out.println("after_change_"+op);
    }
}
```

Prints **before change 50** - **after change 150** operates on reference to itself and toString is called automatically by System.out.println.

Summary: Object Orientation

Data type: set of values and collections of operations on those values.

In OOP: **classes**.

Simulating the physical world

- ▶ Java objects can be used to model real-world objects
- ▶ Not necessarily easy to choose good modelling primitives, or to get model that reflects relevant parts of reality.
- ▶ Examples: geometric figures, hotel rooms, . . .

Extending the Java language

- ▶ Java doesn't have a data type for every possible application.
- ▶ User-defined classes enable us to add our own abstractions.

Summary: designing a Java class

- ▶ Use client code to motivate and test classes.
- ▶ **instance variables:**
 - ▶ represent data that is particular to an object (i.e., an instance!);
 - ▶ have scope over the whole class;
 - ▶ can hold mutable state;
 - ▶ can be manipulated by any instance method in the class.
- ▶ **instance methods:**
 - ▶ like static methods, but can only be called on some object `o`;
 - ▶ have access to the data that is specific to `o`.
- ▶ **constructors:**
 - ▶ we create a new object of class `Foo` with the keyword `new`;
 - ▶ we initialise an object of type `Foo` by calling the constructor for that type;
 - ▶ the constructor can be used to store data values in the object's instance variables.

Reading

Objects First

Chapter 2 *Understanding Class Definitions*

Java Tutorial

pp99-121, i.e. continuing with Chapter 4 *Classes and Objects*,
stopping at *Nested Classes*

We haven't talked about inheritance or interfaces (yet), but
everything else should be looking familiar.
