We want to investigate the relationship between the number of bikes hired in an hour and the mean temperature during that hour

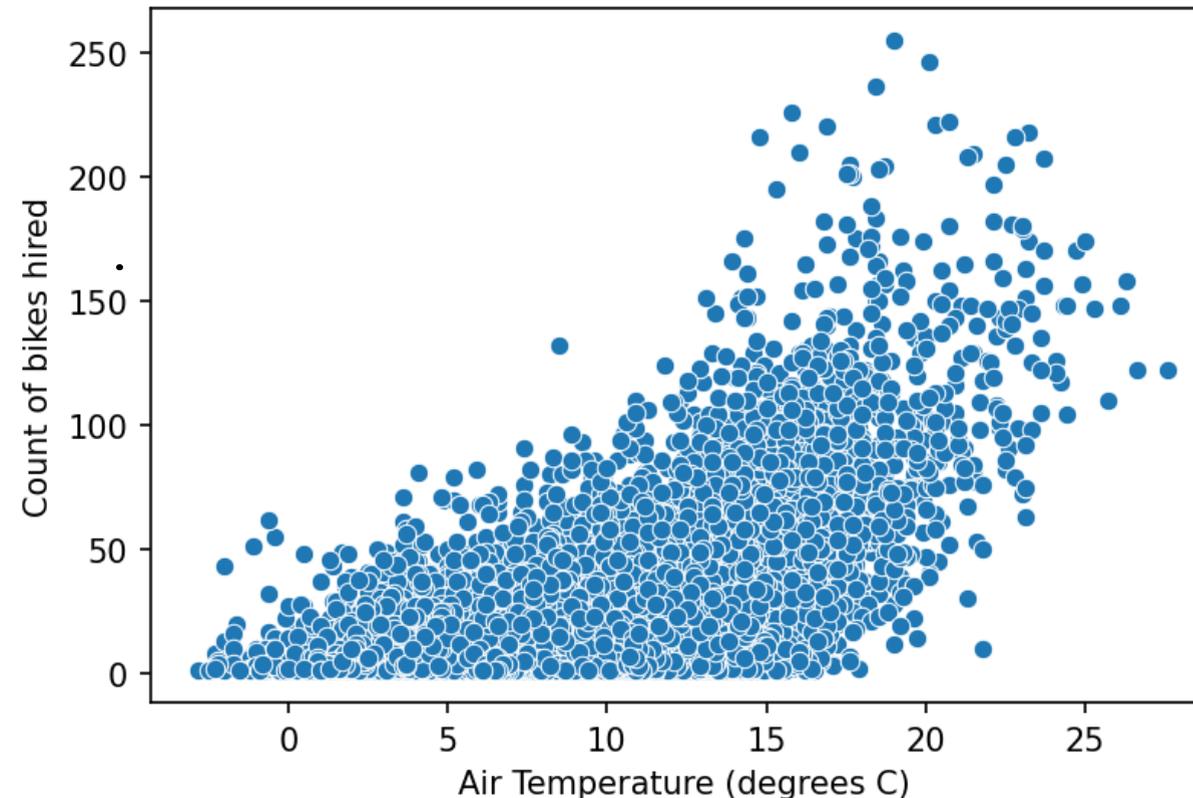

Is there a problem with using ordinary least squares linear regression to do this?

- Edinburgh temperature observations, Met Office via MIDAS

Where we're at in the Maximum Likelihood Principle and Regression

Overview

Today

1. The maximum likelihood principle
2. Application of maximum likelihood to a simple example
3. Application of maximum likelihood to linear regression

Wednesday

- Max likelihood with non-normal distributions
- Generalised linear regression, including logistic regression

**Inf2 - Foundations of Data Science:

Intuition for maximum likelihood principle

Statistical model, e.g. normal dist.

Data

$$p(y | \mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2} \frac{(y-\mu)^2}{\sigma^2}}$$

Given a normal distribution, what parameters are most likely to have generated data?

Exercise

Which model is most likely to have generated this data?

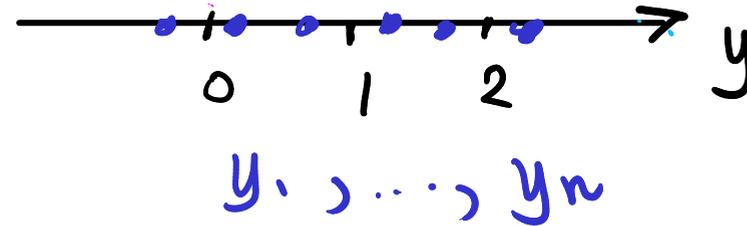

① $y_i \sim \mathcal{N}(\overset{\mu}{0}, \overset{\sigma^2}{1})$

② $y_i \sim \mathcal{N}(1, 0.1)$

③ $y_i \sim \mathcal{N}(1, 5)$

④ $y_i \sim \mathcal{N}(1, 1)$

Data

Definition of Principle of Maximum Likelihood

For a set of observed data and a given statistical model the principle of maximum likelihood states that the parameters of the model are adjusted so as to maximise the likelihood that the model generated the observed data.

Data : $\{y_1, \dots, y_n\}$

Likelihood $P(\underline{y} = y_1, \dots, y_n | \vartheta_1, \dots, \vartheta_m)$

Normal : $\vartheta_1 = \mu$
 $\vartheta_2 = \sigma^2$

Application to 1-variable example

1. Assume samples are drawn independently
2. Assume each sample is drawn from a normal distribution

More compact notation...

Likelihood

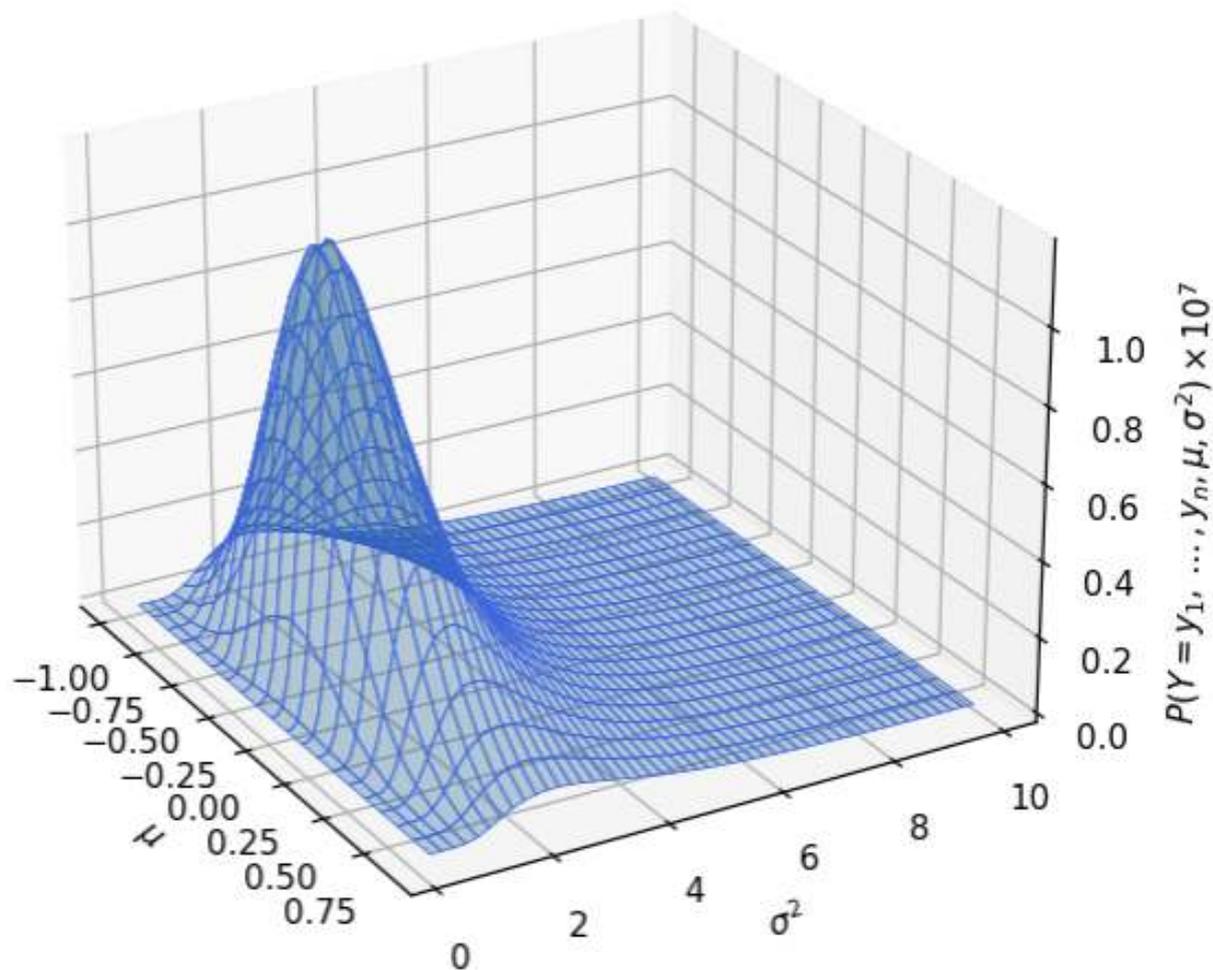

$$P(\underline{y} = y_1, \dots, y_n) = P(Y = y_1 | \mu, \sigma^2) \\ \times P(Y = y_2 | \mu, \sigma^2) \\ \times \dots \\ \times P(Y = y_n | \mu, \sigma^2)$$

Likelihood as a function of parameters

Data:

y_1, \dots, y_{10} drawn from
 $\mathcal{N}(0, 1)$

	Data
y_1	1.624345
y_2	-0.611756
y_3	-0.528172
y_4	-1.072969
y_5	0.865408
y_6	-2.301539
y_7	1.744812
y_8	-0.761207
y_9	0.319039
y_{10}	-0.249370

[code]

Log-likelihood equations: products to sums

Remember: $\ln a b = \ln a + \ln b$

$$\ln(p_1 \times \dots \times p_n) = \ln p_1 + \dots + \ln p_n$$

$$\ln \left(\prod_{i=1}^n p_i \right) = \sum_{i=1}^n \ln p_i$$

Log likelihood

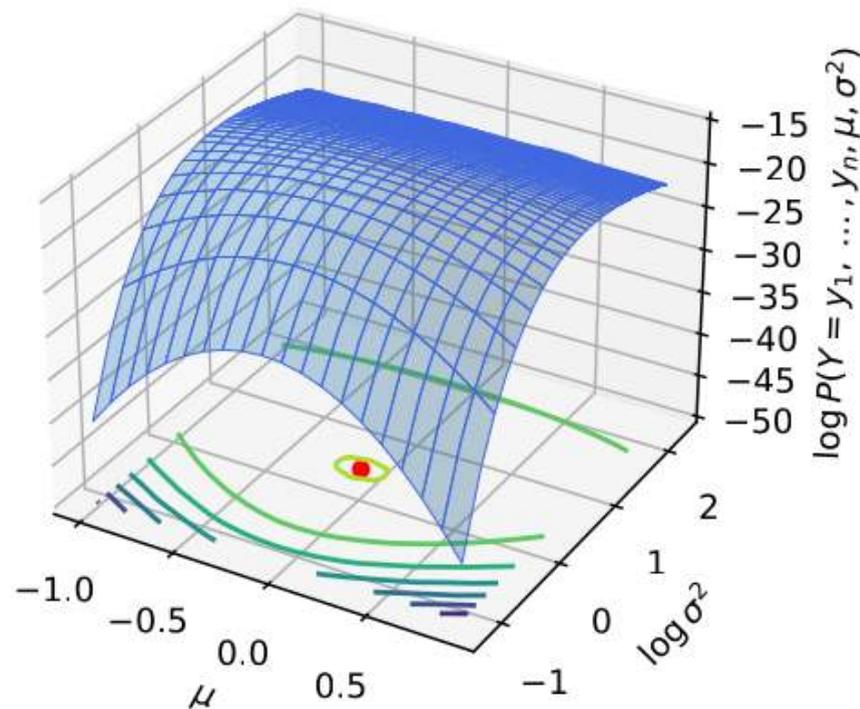

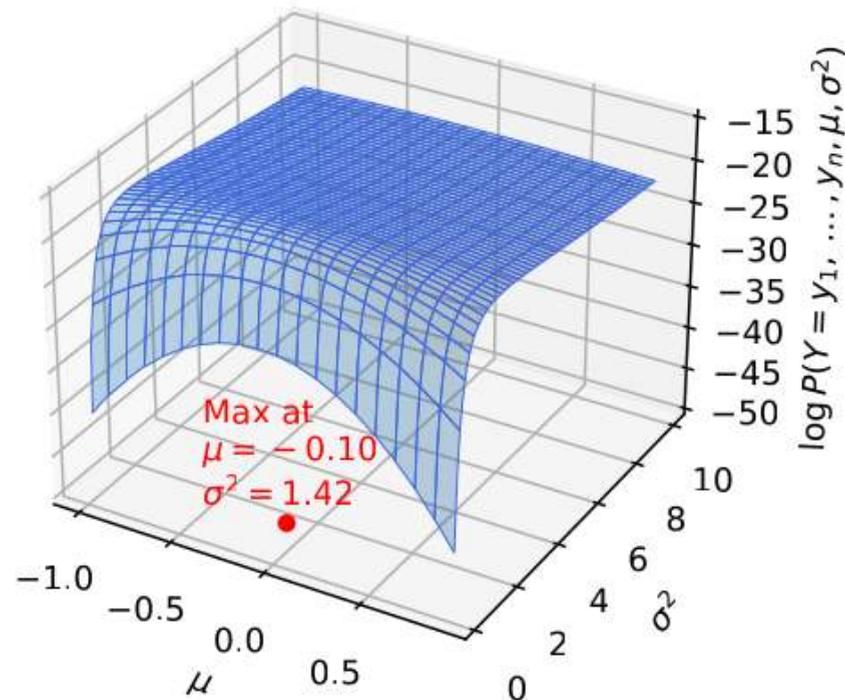

$$\ln \left(\prod_{i=1}^n P(y = y_i | \mu, \sigma^2) \right) = \sum_{i=1}^n \ln P(y = y_i | \mu, \sigma^2)$$

The log of the normal distribution

$$\begin{aligned}\ln P(Y=y_i | \mu, \sigma^2) &= \ln \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2} \\ &= \ln\left(\frac{1}{\sqrt{2\pi}\sigma}\right) + \left(-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right) \\ &= -\frac{1}{2}\ln 2\pi\sigma^2 - \frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\end{aligned}$$

Log-likelihood of data drawn from a normal distribution as a function of parameters

$$\begin{aligned} \ln P(\underline{Y} = y_1, \dots, y_n \mid \mu, \sigma^2) \\ = \sum_{i=1}^n \left(-\frac{1}{2} \ln 2\pi\sigma^2 - \frac{1}{2} \frac{(y_i - \mu)^2}{\sigma^2} \right) \end{aligned}$$

Maximum likelihood estimates of parameters

$$\begin{aligned} & \ln P(\underline{y} = y_1, \dots, y_n \mid \mu, \sigma^2) \\ & = \sum_{i=1}^n \left(-\frac{1}{2} \ln 2\pi\sigma^2 - \frac{1}{2} \frac{(y_i - \mu)^2}{\sigma^2} \right) \end{aligned}$$

Maximise w.r.t μ and σ^2 to give max likelihood estimates (MLE)

$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^n y_i$$

$$\hat{\sigma}_2 = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{\mu})^2$$

Exercise: prove these statements by differentiating w.r.t. μ and σ^2

The beauty of logs and sums

- Sum of logs is easy to represent within limits of floating point arithmetic
- Log likelihood function is smoother than likelihood function
- Sums are easy to differentiate; products are not

Application of max likelihood to linear regression

$$\hat{y}_i = \beta_0 + \beta_1 x_i$$

$$y_i = \beta_0 + \beta_1 x_i + \underbrace{\varepsilon_i}_{\text{error term}}$$

Relationship to ordinary least squares

$$\begin{aligned} \ln p(y_1, \dots, y_n; x_1, \dots, x_n | \beta_0, \beta_1, \sigma^2) \\ &= \sum_{i=1}^n \left(-\frac{1}{2} \ln 2\pi\sigma^2 - \frac{1}{2} \frac{(y_i - \beta_0 - \beta_1 x_i)^2}{\sigma^2} \right) \\ &= -\frac{n}{2} \ln 2\pi\sigma^2 - \underbrace{\frac{1}{2\sigma^2} \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2}_{\text{SSE}} \end{aligned}$$

Estimate of coefficients

- Analytical solutions for $\hat{\beta}_0$, $\hat{\beta}_1$ and $\hat{\sigma}^2$ that maximise like lihood
- $\hat{\beta}_0$ and $\hat{\beta}_1$: as per ordinary least squares
- Variance of residuals:

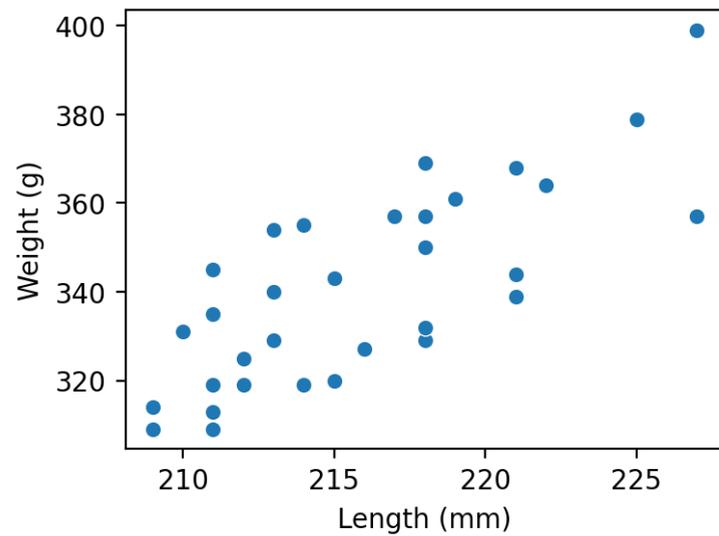

$$\begin{aligned}\hat{\sigma}^2 &= \frac{1}{n} \sum_{i=1}^n (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i)^2 \\ &= \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 = \frac{SSE}{n} \leftarrow \text{Biased}\end{aligned}$$

Sampling theory $\hat{\sigma}^2 = \frac{SSE}{n-2} \leftarrow \text{Unbiased}$

Overview

1. Maximum likelihood principle
 - What model was most likely to have generated the data
2. Maximum likelihood principle applied to simple example
 - Log likelihood turns out to be useful
 - Gives rise to familiar estimates for mean and variance
3. Maximum likelihood principle applied to linear regression
 - Turns out to give ordinary least squares
 - Link with coefficient uncertainty and the bootstrap estimates of parameter uncertainty

We want to investigate the relationship between the number of bikes hired in an hour and the mean temperature during that hour

Is there a problem with using ordinary least squares linear regression to do this?
