Review: Summary of algorithms

Review: Tree search

function TREE-SEARCH(*problem*) **returns** a solution, or failure

initialize the frontier using the initial state of *problem*

loop do

if the frontier is empty **then return** failure

 choose a leaf node and remove it from the frontier

if the node contains a goal state **then return** the corresponding solution

 expand the chosen node, adding the resulting nodes to the frontier

A *search strategy* is defined by picking the order of node expansion from the **frontier**.

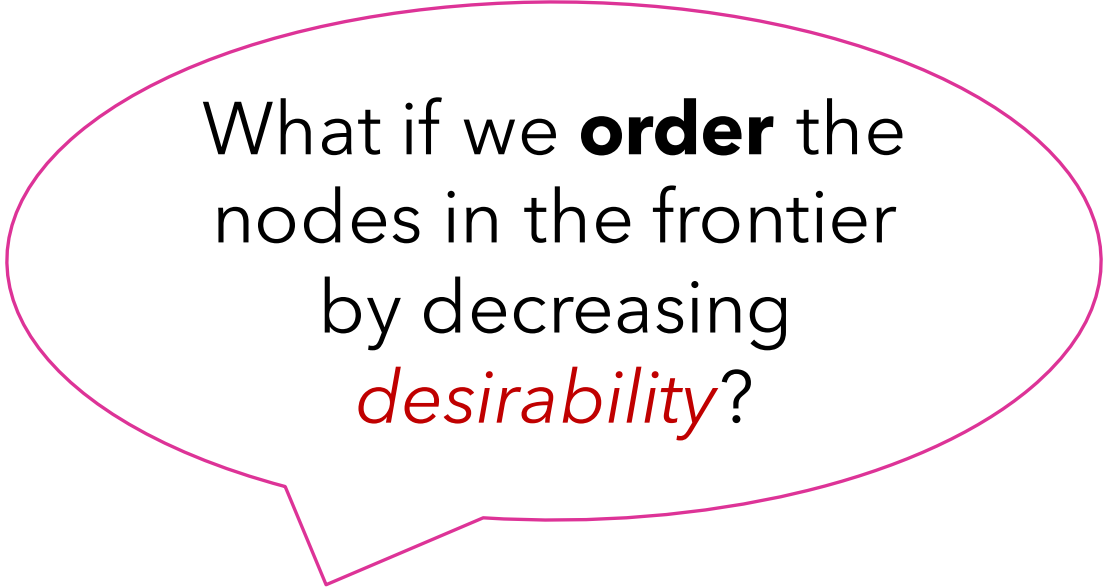

Review: Graph search

```
function GRAPH-SEARCH(problem) returns a solution, or failure
  initialize the frontier using the initial state of problem
  initialize the explored set to be empty
  loop do
    if the frontier is empty then return failure
    choose a leaf node and remove it from the frontier
    if the node contains a goal state then return the corresponding solution
    add the node to the explored set
    expand the chosen node, adding the resulting nodes to the frontier
      only if not in the frontier or explored set
```

A *search strategy* is defined by picking the order of node expansion from the **frontier**.

Making search 'informed'

- Tree-Search
- Graph Search

What if we **order** the nodes in the frontier by decreasing *desirability*?

A *search strategy* is defined by picking the order of node expansion from the **frontier**.

Best-first search

An instance of general TREE-SEARCH or GRAPH-SEARCH

→ Use an evaluation function $f(n)$ for each node n

- estimate of "desirability"

→ Expand **most desirable** unexpanded node, usually the node with the **lowest** evaluation

Heuristics

- Any method that is believed or practically proven to be **useful for the solution** of a given problem.
 - No guarantee that it will always work or lead to an optimal solution!
- We use heuristics to **guide search**.
 - This may not change the worst-case complexity of the algorithm, but can help in the average case.
- We will introduce **admissibility, consistency** conditions to identify good heuristics.

Romania Example

Greedy best-first search

Greedy best-first search

- Evaluation function $f(n) = h(n)$ (heuristic)
 - **estimated cost** of cheapest path from state at node n to a *goal* state
 - e.g., $h_{SLD}(n)$ = straight-line distance from n to Bucharest
- Greedy best-first search expands the node that **appears** to be closest to goal.

No

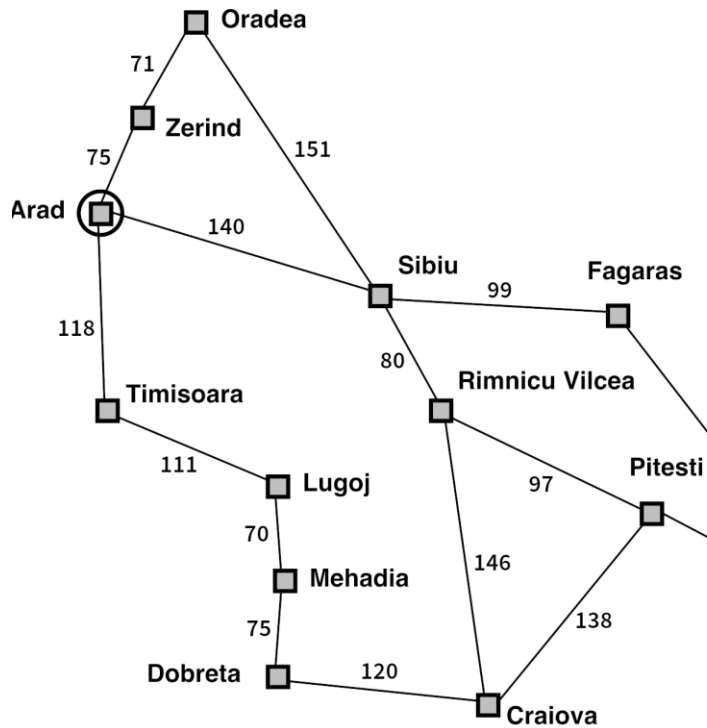

A* Search

A* search

- Evaluation function $f(n) = g(n) + h(n)$
 - $g(n)$ = cost so far to reach n
 - $h(n)$ = estimated cost from n to goal
 - $f(n)$ = estimated total cost of path through n to goal
- Avoid expanding paths that are already **expensive**

Heuristics

Admissible heuristics

- A heuristic $h(n)$ is **admissible** if for every node n :

$$h(n) \leq \mathbf{h^*(n)}$$

where $\mathbf{h^*(n)}$ is the **true** cost to reach the goal state from n .

- An admissible heuristic never overestimates the cost to reach the goal, i.e., it is **optimistic**

Example: $h_{SLD}(n)$ (never overestimates the actual road distance)

Admissible heuristic = optimal A*

$h(n)$ never overestimates the cost to reach the goal

Thus, $f(n) = g(n) + h(n)$ never overestimates the true cost of a solution

THEOREM

If $h(n)$ is admissible, A* using **TREE-SEARCH** is optimal

Proof: Optimality of A^*

Suppose some **suboptimal** goal G_2 has been generated and is in the frontier.

Let n be an unexpanded node in the frontier such that n is on a **shortest path** to an **optimal** goal G .

$$f(G_2) = g(G_2)$$

$$\text{since } h(G_2) = 0$$

$$g(G_2) > g(G)$$

since G_2 is suboptimal

$$f(G) = g(G)$$

$$\text{since } h(G) = 0$$

$$f(G_2) > f(G)$$

from above

Proof: Optimality of A*

Suppose some **suboptimal** goal G_2 has been generated and is in the frontier.

Let n be an unexpanded node in the frontier such that n is on a **shortest path** to an **optimal** goal G .

$$f(G) < f(G_2) \quad \text{from above}$$

$$h(n) \leq h^*(n) \quad \text{since } h \text{ is admissible}$$

$$g(n) + h(n) \leq g(n) + h^*(n)$$

$$f(n) \leq f(G)$$

Hence $f(n) < f(G_2)$, and A will never select G_2 for expansion*

Consistent heuristics

A heuristic $h(n)$ is **consistent** if for every node n , every successor n' of n generated by any action a ,

$$h(n) \leq c(n, a, n') + h(n')$$

If h is consistent, we have

$$\begin{aligned} f(n') &= g(n') + h(n') \\ &= g(n) + c(n, a, n') + h(n') \\ &\geq g(n) + h(n) \\ &\geq f(n) \end{aligned}$$

i.e., $f(n)$ is non-decreasing along any path.

THEOREM

If $h(n)$ is consistent, A^* using **GRAPH-SEARCH** is **optimal**

Optimality of A^*

A^* expands nodes in order of increasing f value

Gradually adds " f -contours" of nodes

Contour i has all nodes with $f=f_i$, where $f_i < f_{i+1}$

Properties of A^*

Complete?

Time complexity?

Space complexity?

Keeps all nodes in memory

Optimal?

Yes

Admissible heuristics

Example: 8-puzzle:

- $h_1(n)$ = number of misplaced tiles
- $h_2(n)$ = total Manhattan distance

(i.e., no. of squares from desired location of each tile)

$$h_1(S) = ?$$

$$h_2(S) = ?$$

7	2	4
5		6
8	3	1

Start State

	1	2
3	4	5
6	7	8

Goal State

Relaxed problems

- A problem with fewer restrictions on the actions is called a *relaxed problem*.
- The cost of an optimal solution to a relaxed problem is an *admissible heuristic for the original problem*.
- If the rules of the 8-puzzle are relaxed so that a tile can move anywhere,
 - then $h_1(n)$ gives the shortest solution
- If the rules are relaxed so that a tile can move to any adjacent square,
 - then $h_2(n)$ gives the shortest solution

Use relaxation to automatically generate admissible heuristics!

Dominance

- If $h_2(n) \geq h_1(n)$ for all n (both admissible) then
 - h_2 dominates h_1
 - h_2 is better for search
- Typical search costs (*average number of nodes expanded*):
 - $d=12$ IDS = 3,644,035 nodes
 $A^*(h_1) = 227$ nodes
 $A^*(h_2) = 73$ nodes
 - $d=24$ IDS \approx 54,000,000,000 nodes
 $A^*(h_1) = 39,135$ nodes
 $A^*(h_2) = 1,641$ nodes

Summary

Smart search based on **heuristic scores**.

- Best-first search
- Greedy best-first search
- A* search
- Admissible heuristics and optimality.

Why?

- Informed search allows us to use **domain knowledge** to our advantage.
- **Optimality** over some utility can often be the top priority.
- A* is **very** popular! (e.g., pathfinding)
- A* is simple, yet very efficient.
- A* is *too good* sometimes (e.g., in games).
