Constraint satisfaction problems (CSPs)

State

- Set of *variables* X_i with values from domain D_i

Actions

- *Assign* a value to a variable

Goal test

- A set of *constraints* specifying allowable combinations of values for subsets of variables

Path cost

- None

Constraint satisfaction problems (CSPs)

State

- Set of *variables* X_i with values from domain D_i

Actions

- *Assign* a value to a variable

Goal test

- A set of *constraints* specifying allowable combinations of values for subsets of variables

Pa

Simple example of a *formal representation language*.

Allows useful general-purpose algorithms with more power than standard search algorithms.

Structure of a CSP

- A set of **variables**: $X = \{X_1, \dots, X_n\}$
- A set of **domains**: $D = \{D_1, \dots, D_n\}$
 - each domain D_i is a set of possible values for variable X_i
- A set of **constraints** C that specify acceptable combinations of values.
 - Each $c \in C$ consists of:
 - a **scope** - tuple of variables (neighbours) involved in the constraint
 - a **relation** that defines the values that the variables can take

Example: Map-Colouring

Variables: $\{WA, NT, Q, NSW, V, SA, T\}$

Domains: $D_i = \{\text{red}, \text{green}, \text{blue}\}$

Constraints: adjacent regions must have different colours,

- e.g. $WA \neq NT$,
- or $(WA, NT) \in \{(\text{red}, \text{green}), (\text{red}, \text{blue}), (\text{green}, \text{red}), (\text{green}, \text{blue}), (\text{blue}, \text{red}), (\text{blue}, \text{green})\}$.

Example: Map-Colouring

Solutions are *complete* and *consistent* assignments,

- e.g., WA = red, NT = green, Q = red,
NSW = green, V = red, SA = blue, T = green.

Constraint graph

Binary CSP:

each constraint relates two variables.

Constraint graph:

nodes are variables, arcs are constraints.

Constraint graph

Binary CSP:

each constraint relates two variables.

Constraint graph:

nodes are variables, arcs are constraints.

Varieties of CSPs

Discrete variables:

- finite domains:
 - n variables, domain size $d \rightarrow O(d^n)$, complete assignments.
 - e.g., Boolean CSPs, incl. Boolean satisfiability (NP-complete).
- infinite domains:
 - integers, strings, etc.
 - e.g., job scheduling, variables are start/end days for each job.
 - need a constraint language, e.g. $StartJob_1 + 5 \leq StartJob_3$.

Continuous variables:

- e.g. start/end times for Hubble Space Telescope observations.
- linear constraints solvable in polynomial time by linear programming.

Real-world CSPs

Assignment problems

e.g., who teaches what class.

Timetabling problems

e.g., which class is offered when and where.

Transportation scheduling

Factory scheduling

¹¹⁺ 5	²⁺ 6	3	^{20x} 4	^{6x} 1	2
6	³⁻ 1	4	5	³⁺ 2	3
^{240x} 4	5	^{6x} 2	3	6	1
3	4	^{6x} 1	⁷⁺ 2	^{30x} 5	6
^{6x} 2	3	6	1	4	⁹⁺ 5
⁸⁺ 1	2	5	²⁺ 6	3	4

Games

*Notice that many real-world problems involve **real-valued** variables.*

Varieties of constraints

Unary constraints involve a single variable,

- e.g., $SA \neq \text{green}$.

Binary constraints involve pairs of variables,

- e.g., $SA \neq WA$.

Higher-order constraints involve 3 or more variables,

- e.g., crypt-arithmetic column constraints.

Global constraints involve an arbitrary number of variables

Example: Crypt-arithmetic

$$\begin{array}{r}
 T W O \\
 + T W O \\
 \hline
 F O U R
 \end{array}$$

Variables: $FTUWROX_1X_2X_3$.

Domains: $\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$.

Constraints:

- $Alldiff(F, T, U, W, R, O)$ ← Global constraint
- $O + O = R + 10 \cdot X_1$
- $X_1 + W + W = U + 10 \cdot X_2$
- $X_2 + T + T = O + 10 \cdot X_3$
- $X_3 = F, T \neq 0, F \neq 0$

Search in CSPs

Standard search formulation (incremental)

- States are defined by the **values** assigned so far.

Initial state: the empty assignment { }

Successor function:

assign a value to an unassigned variable that does not conflict with current assignment

→ fail if no legal assignments.

Goal test: the current assignment is complete.

- For a CSP with n variables, every solution appears at depth n
→ use depth-first search!

Backtracking search

- Variable assignments are *commutative*,
 - e.g., [WA = red then NT = green] same as [NT = green then WA = red].
- Only need to consider assignments to a *single variable at each node*
- Depth-first search for CSPs with single-variable assignments is called *backtracking* search.
- Backtracking search is the basic *uninformed algorithm* for CSPs.

8-queens problem

function BACKTRACKING-SEARCH(*csp*) **returns** a solution, or failure
return BACKTRACK({ }, *csp*)

function BACKTRACK(*assignment*, *csp*) **returns** a solution, or failure
if *assignment* is complete **then return** *assignment*
var ← SELECT-UNASSIGNED-VARIABLE(*csp*)
for each *value* **in** ORDER-DOMAIN-VALUES(*var*, *assignment*, *csp*) **do**
 if *value* is consistent with *assignment* **then**
 add {*var* = *value*} to *assignment*
 inferences ← INFERENCE(*csp*, *var*, *value*)
 if *inferences* ≠ *failure* **then**
 add *inferences* to *assignment*
 result ← BACKTRACK(*assignment*, *csp*)
 if *result* ≠ *failure* **then**
 return *result*
 remove {*var* = *value*} and *inferences* from *assignment*
return *failure*

Backtracking search

Backtracking example

Can we eliminate some symmetrical nodes?

Backtracking example

Can we eliminate some symmetrical nodes?

Backtracking example

Smart Search in CSPs

... or how to improve from backtracking

```

function BACKTRACKING-SEARCH(csp) returns a solution, or failure
  return BACKTRACK({ }, csp)

function BACKTRACK(assignment, csp) returns a solution, or failure
  if assignment is complete then return assignment
  var ← SELECT-UNASSIGNED-VARIABLE(csp)
  for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
    if value is consistent with assignment then
      add { var = value } to assignment
      inferences ← INFERENCE(csp, var, value)
      if inferences ≠ failure then
        add inferences to assignment
        result ← BACKTRACK(assignment, csp)
        if result ≠ failure then
          return result
      remove { var = value } and inferences from assignment
  return failure

```

Improving backtracking efficiency

General-purpose methods can give huge gains in speed:

- Which **variable** should be assigned next?
 - **SELECT-UNASSIGNED-VARIABLE**
- In what order should its **values** be tried?
 - **ORDER-DOMAIN-VALUES**
- What **inferences** should be performed at each step of the search?
 - **INFERENCE**
- Can we detect inevitable failure **early**?

Most constrained variable

```
var ← SELECT-UNASSIGNED-VARIABLE (csp)
```

- Most constrained variable:
 - choose the variable with the *fewest* legal values.
- a.k.a. *minimum-remaining-values* (MRV) heuristic.

The Degree Heuristic

- Good to identify an **initial state**
- Tie-breaker among **most constrained** variables.
- Most constraining variable:
 - choose the variable with the **most constraints** on remaining variables thus **reducing branching**.

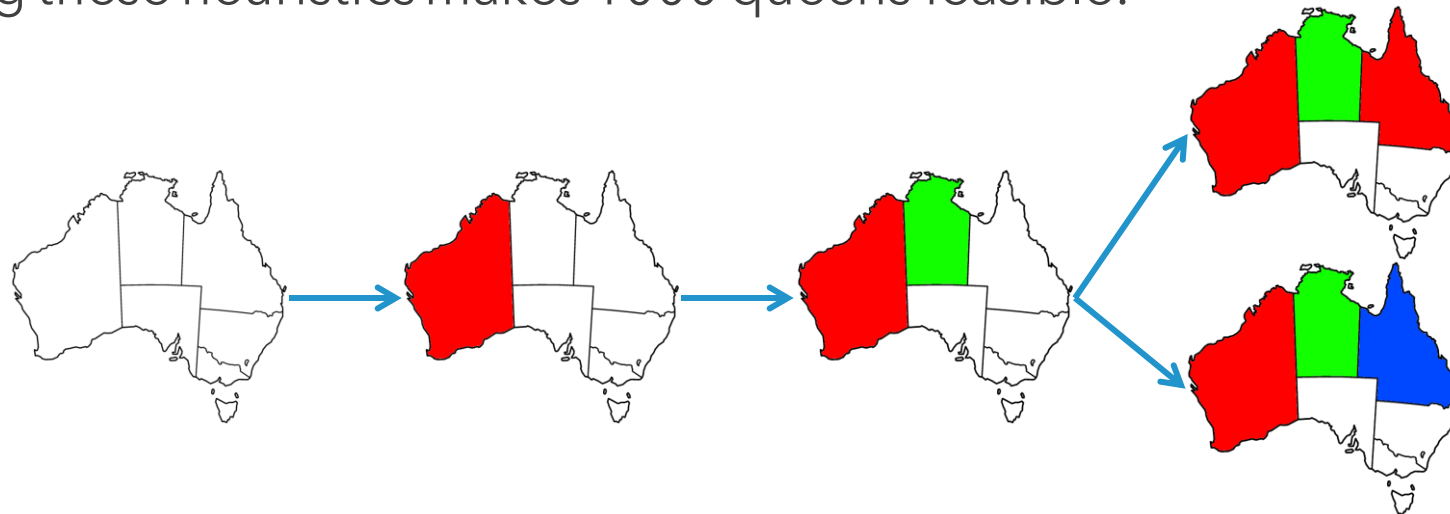

Least constraining value

for *value* in ORDER-DOMAIN-VALUES(*var*, *assignment*, *csp*)

- Least constraining value:
 - *given a variable, choose the value that rules out the fewest values in the remaining variables.*
 - Combining these heuristics makes 1000 queens feasible!

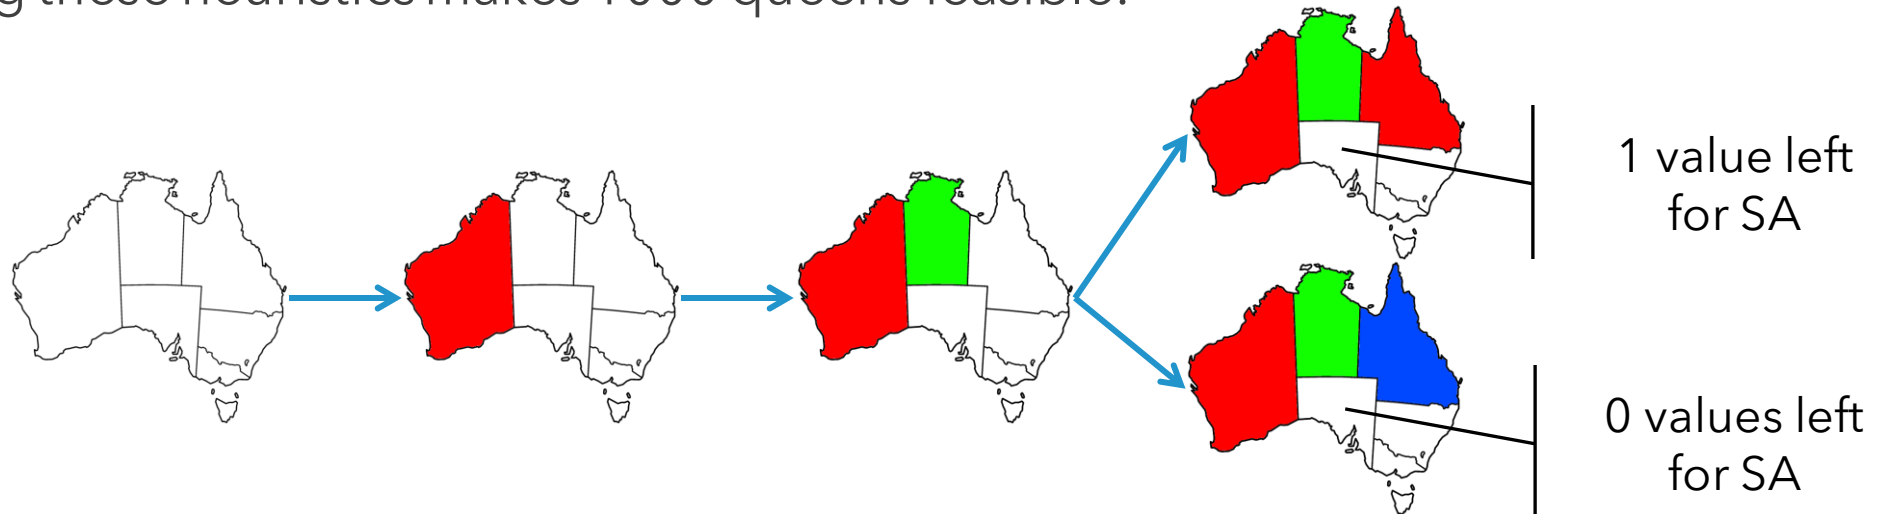

Least constraining value

for *value* in ORDER-DOMAIN-VALUES(*var*, *assignment*, *csp*)

➤ Least constraining value:

- *given a variable, choose the value that rules out the fewest values in the remaining variables.*
- Combining these heuristics makes 1000 queens feasible!

Variable Ordering

Value Ordering

Inference

Constraint propagation

Forward checking propagates information from assigned to unassigned variables, but doesn't provide **early** detection for all failures:

WA	NT	Q	NSW	V	SA	T
Red Green Blue	Red Green Blue	Red Green Blue	Red Green Blue	Red Green Blue	Red Green Blue	Red Green Blue
Red Red Red	Green Blue	Red Green Blue	Red Green Blue	Red Green Blue	Green Blue	Red Green Blue
Red Red Red	Blue	Green Green Green	Red Blue	Red Green Blue	Blue	Red Green Blue

NT and SA cannot both be blue!

Constraint propagation repeatedly enforces constraints locally.

Arc consistency

Simplest form of propagation makes each arc **consistent**.

$X \rightarrow Y$ is **consistent** iff for **every** value x of in the domain of X there is **some** allowed y in the domain of Y .

Is there a value for X that makes the domain of Y empty?

Can be run as a preprocessor or after each assignment.

Start with all directed arcs from the graph (18 here):

$WA \rightarrow NT, WA \rightarrow SA, NT \rightarrow WA, NT \rightarrow SA, NT \rightarrow Q, Q \rightarrow NT, Q \rightarrow SA,$
 $Q \rightarrow NSW, SA \rightarrow WA, SA \rightarrow NT, SA \rightarrow Q, SA \rightarrow NSW, SA \rightarrow V,$
 $NSW \rightarrow Q, NSW \rightarrow SA, NSW \rightarrow V, V \rightarrow SA, V \rightarrow NSW$

Variable

Ordering

Inference

Arc consistency

$X \rightarrow Y$: Is there a value for X that makes the domain of Y empty?

e.g. NSW \rightarrow SA

WA	NT	Q	NSW	V	SA	T
Red	Blue	Green	Red X	Red Green Blue	Blue	Red Green Blue

Variable
Ordering

Value
Ordering

Inference

Arc consistency

$X \rightarrow Y$: Is there a value for X that makes the domain of Y empty?

e.g. NSW \rightarrow SA

Once a value is removed, add all arcs pointing to X back in the queue!

WA	NT	Q	NSW	V
Red	Blue	Green	Red	Red, Green, Blue

Domain of NSW became smaller, so some arcs may have become *inconsistent*!

Arc consistency

$X \rightarrow Y$: Is there a value for X that makes the domain

e.g. NSW \rightarrow SA

Once a value is removed, add all arcs pointing to X back in the queue!

Add:
 $V \rightarrow$ NSW
 $SA \rightarrow$ NSW
 $Q \rightarrow$ NSW

WA	NT	Q	NSW	V	SA	T

Arc consistency

$X \rightarrow Y$: Is there a value for X that makes the domain

e.g. NSW \rightarrow SA

Once a value is removed, add all arcs pointing to X back in the queue!

Add:
 $V \rightarrow$ NSW
 $SA \rightarrow$ NSW
 $Q \rightarrow$ NSW

WA	NT	Q	NSW	V	SA	T
				✗		

Variable
Ordering

Value
Ordering

Inference

Arc consistency

$X \rightarrow Y$: Is there a value for X that makes the domain of Y empty?

Eventually check $SA \rightarrow NT$

WA	NT	Q	NSW	V	SA	T
Red	Blue	Green	Red	Green, Blue	Blue	Red, Green, Blue

Variable Ordering

Value Ordering

Inference

Arc consistency

$X \rightarrow Y$: Is there a value for X that makes the domain of Y empty?

Eventually check $SA \rightarrow NT$

WA	NT	Q	NSW	V	SA	T
Red	Blue	Green	Red	Green, Blue	Blue	Red, Green, Blue

Variable Ordering

Value Ordering

Inference

Arc consistency

$X \rightarrow Y$: Is there a value for X that makes the domain of Y empty?

Eventually check $SA \rightarrow NT$

WA	NT	Q	NSW	V	SA	T
Red	Blue	Green	Red	Green Blue	Fail!	Red Green Blue

Arc consistency detects failure earlier than forward checking.

Variable
Ordering

Value
Ordering

Inference

Arc consistency algorithm AC-3

function AC-3(*csp*) **returns** false if an inconsistency is found and true otherwise

inputs: *csp*, a binary CSP with components (X, D, C)

local variables: *queue*, a queue of arcs, initially all the arcs in *csp*

while *queue* is not empty **do**

$(X_i, X_j) \leftarrow \text{REMOVE-FIRST}(\textit{queue})$

if REVISE(*csp*, X_i, X_j) **then** ← **Make X_i arc-consistent with respect to X_j**

if size of $D_i = 0$ **then return** false ← **No consistent value left for X_i so fail**

for each X_k **in** $X_i.\text{NEIGHBORS} - \{X_j\}$ **do**

 add (X_k, X_i) to *queue* ← **Since revision occurred, add all neighbours of X_i for consideration (or reconsideration)**

return true

Time complexity: $O(cd^3)$,
where:

➤ d is maximum size of each domain,

➤ c is the number of binary constraints (arcs).

function REVISE(*csp*, X_i, X_j) **returns** true iff we revise the domain of X_i

revised \leftarrow false

for each x **in** D_i **do**

if no value y in D_j allows (x,y) to satisfy the constraint between X_i and X_j **then**

 delete x from D_i

revised \leftarrow true

return *revised*

Summary

- CSPs are a special kind of problem:
 - states defined by **values** of a fixed set of **variables**
 - goal test defined by **constraints** on variable values
- Backtracking = depth-first search with **one variable assigned per node**
- **Variable ordering** and **value selection** heuristics help significantly
- **Forward checking** prevents assignments that guarantee later failure
- **Constraint propagation** (e.g., arc consistency) does additional work to constrain values and detect inconsistencies

Why?

- CSPs are prevalent in modern computation.
- Examples include: resource allocation, planning & scheduling, automated configuration, puzzles/games.
- More complex problem formulations exist: e.g., Distributed Constraint Optimisation Problems (DCOPs).
- Other solutions exist too: e.g., genetic algorithms, optimization
