### Informatics 2D: Reasoning and Agents

#### Slides provided by Prof. Alex Lascarides

Lecture 16: Introduction to Planning

### Where are we?

The first two blocks of the course dealt with ...

- Basic notions of agency
- Intelligent problem-solving
- Heuristic search, constraints
- Logic & logical reasoning
- Reasoning about actions and time

In the remainder of the course we will talk about ...

• Planning

Uncertainty

### Where are we?

The first two blocks of the course dealt with ...

- Basic notions of agency
- Intelligent problem-solving
- Heuristic search, constraints
- Logic & logical reasoning
- Reasoning about actions and time

In the remainder of the course we will talk about ...

- Planning
- Uncertainty

# What is planning?

- **Planning** is the task of coming up with a sequence of actions that will achieve a goal
- We are only considering **classical planning** in which environments are
  - fully observable (accessible),
  - deterministic,
  - finite,
  - static (up to agents' actions),
  - discrete (in actions, states, objects and events).
- (Lifting some of these assumptions will be the subject of the "uncertainty" part of the course)

Problems with Search Problems with Logic

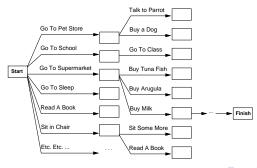

- So far we have dealt with two types of agents:
  - Search-based problem-solving agents
  - 2 Logical planning agents
- Do these techniques work for solving planning problems?

Problems with Search Problems with Logic

# Why planning?

- Consider a search-based problem-solving agent in a robot shopping world
- Task: Go to the supermarket and get milk, bananas and a cordless drill
- What would a search-based agent do?

Problems with Search Problems with Logic

# Problems with search

- No goal-directedness.
- No problem decomposition into sub-goals that build on each other
  - May undo past achievements
  - May go to the store 3 times!
- Simple goal test doesn't allow for the identification of milestones
- How do we find a good heuristic function? How do we model the way humans perceive complex goals and the quality of a plan?

Problems with Search Problems with Logic

# How about logic & deductive inference?

- Generally a good idea, allows for "opening up" representations of states, actions, goals and plans
- If Goal = Have(Bananas) ∧ Have(Milk) this allows achievement of sub-goals (if independent)
- Current state can be described by properties in a compact way (e.g. *Have*(*Drill*) stands for hundreds of states)
- Allows for compact description of actions, for example

 $Object(x) \Rightarrow Can(a, Grab(x))$ 

 Allows for representing a plan hierarchically,
 e.g. GoTo(Supermarket) = Leave(House) *ReachLocationOf*(Supermarket) *Leave*(House) *ReachLocationOf*(Supermarket) *then* decompose further into sub-plans

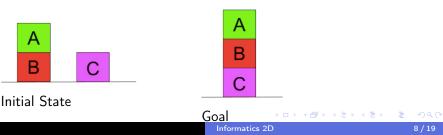

Problems with Search Problems with Logic

# How about logic & deductive inference?

### Problems:

- In its general form either awkward (propositional logic) or tractability problems (first-order logic)
- If p is a sequence that achieves the goal, then so is [a, a<sup>-1</sup>|p]!
- (Logically independent) subgoals may need to be undone to achieve other goals.

Goal:  $on(A, B) \land on(B, C)$ 

Problems with Search Problems with Logic

### Solutions: We need

- It reduce complexity to allow scaling up.
- **②** To allow reasoning to be guided by plan 'quality'/efficiency.
- Do 1. next, and 2. after that.

PDDL

## Representing planning problems

- Need a language expressive enough to cover interesting problems, restrictive enough to allow efficient algorithms.
- Planning Domain Definition Language or PDDL
- PDDL will allow you to express:
  - states
  - actions: a description of transitions between states
  - and goals: a (partial) description of a state.

PDDL

### Representing States and Goals in PDDL

- **States** represented as conjunctions of propositional or function-free first order positive literals:
  - Happy ∧ Sunshine, At(Plane<sub>1</sub>, Melbourne) ∧ At(Plane<sub>2</sub>, Sydney)
- So these aren't states:
  - At(x,y) (no variables allowed), Love(Father(Fred), Fred) (no function symbols allowed) ¬Happy (no negation allowed).

Closed-world assumption!

- A goal is a partial description of a state, and you can use negation, variables etc. to express that description.
  - ¬*Happy*, *At*(*x*,*SFO*), *Love*(*Father*(*Fred*), *Fred*) . . .

< 同 > < 三 > < 三 >

# Actions in PDDL

 $\begin{aligned} &Action(Fly(p, from, to), \\ &Precond: At(p, from) \land Plane(p) \land Airport(from) \land Airport(to) \\ &Effect: \neg At(p, from) \land At(p, to)) \end{aligned}$ 

- Actually action schemata, as they may contain variables
- Action name and parameter list serves to identify the action
- Precondition: defines states in which action is executable:
  - Conjunction of positive and negative literals, where all variables must occur in action name.
- Effect: defines how literals in the input state get changed (anything not mentioned stays the same).
  - Conjunction of positive and negative literals, with all its variables also in the preconditions.
  - Often, effects divided into add list and delete list

PDDL

### The semantics of PDDL: States and their Descriptions

• 
$$s \models At(P_1, SFO)$$
 iff  $At(P_1, SFO) \in s$   
 $s \models \neg At(P_1, SFO)$  iff  $At(P_1, SFO) \notin s$   
 $s \models \phi(x)$  iff there is a ground term  $d$  such that  $s \models \phi[x/d]$ .  
 $s \models \phi \land \psi$  iff  $s \models \phi$  and  $s \models \psi$ 

PDDL

# The Semantics of PDDL: Applicable Actions

Any action is applicable in any state that satisfies the precondition with an appropriate substitution for parameters.
Example: State

 $At(P_1, Melbourne) \land At(P_2, Sydney) \land Plane(P_1) \land Plane(P_2) \land Airport(Sydney) \land Airport(Melbourne) \land Airport(Heathrow)$ 

satisfies

 $At(p, from) \land Plane(p) \land Airport(from) \land Airport(to)$ 

with substitution (among others)

 $\{p/P_2, from/Sydney, to/Heathrow\}$ 

< 同 > < 三 > < 三 >

PDDL

# The semantics of PDDL: The Result of an Action

- Result of executing action a in state s is state s' with any positive literal P in a's Effects added to the state and every negative literal ¬P removed from it (under the given substitution).
- In our example s' would be

 $At(P_1, Melbourne) \land At(P_2, Heathrow) \land Plane(P_1) \land Plane(P_2) \land Airport(Sydney) \land Airport(Melbourne) \land Airport(Heathrow)$ 

- "PDDL assumption": every literal not mentioned in the effect remains unchanged (cf. frame problem)
- Solution = action sequence that leads from the initial state to a state that satisfies the goal.

### Blocks world example

- Given: A set of cube-shaped blocks sitting on a table
- Can be stacked, but only one on top of the other
- Robot arm can move around blocks (one at a time)
- Goal: to stack blocks in a certain way
- Formalisation in PDDL:
  - On(b,x) to denote that block b is on x (block/table)
  - Move(b,x,y) to indicate action of moving b from x to y
  - Precondition for this action requires *Clear*(*z*): nothing stacked on *z*.

## Blocks world example

Action schema:

 $\begin{aligned} & Action(Move(b, x, y), \\ & \mathsf{Precond}: On(b, x) \land Clear(b) \land Clear(y) \\ & \mathsf{Effect}: On(b, y) \land Clear(x) \land \neg On(b, x) \land \neg Clear(y)) \end{aligned}$ 

- Problem: when x = Table or y = Table we infer that the table is clear when we have moved a block from it (not true) and require that table is clear to move something on it (not true)
- Solution: introduce another action

Action(MoveToTable(b,x), Precond: $On(b,x) \land Clear(b)$ Effect: $On(b, Table) \land Clear(x) \land \neg On(b,x)$ )

### Does this Work?

- Interpret Clear(b) as "there is space on b to hold a block" (thus Clear(Table) is always true)
- But without further modification, planner can still use Move(b,x, Table):
  - Needlessly increases search space (not a big problem here, but can be)
- So part of solution is to also add Block(b) ∧ Block(y) to precondition of Move

- Defined the planning problem
- Discussed problems with search/logic
- Introduced PDDL: a special representation language for planning
- Blocks world example as a famous application domain
- Next time: Algorithms for planning! State-Space Search and Partial-Order Planning
