Introduction to Quantum Programming and Semantics

Lecture 13: Clifford circuits

Chris Heunen

University of Edinburgh

Overview

- Clifford circuits and Clifford diagrams
- Graph states with local Clifford operations
- Local complementation, pivoting
- Strong simulation of Clifford circuits
- Synthesis of Clifford circuits

Clifford circuits and Clifford diagrams

Clifford circuits are made from:

$$S = \text{---} \bigcirc_{\pi/2} \text{---} = \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix}$$

$$H = \text{---} \square \text{---} = \text{---} \bigcirc_{\pi/2} \text{---} \bullet_{\pi/2} \text{---} \bigcirc_{\pi/2} \text{---} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

$$CNOT = \begin{array}{c} \text{---} \bigcirc \text{---} \\ | \\ \text{---} \bullet \text{---} \end{array} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

e.g.:

$$Z = \text{---} \bigcirc_{\pi} \text{---} = \text{---} \bigcirc_{\pi/2} \text{---} \bigcirc_{\pi/2} \text{---} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

$$CZ = \begin{array}{c} \text{---} \bigcirc \text{---} \\ | \\ \text{---} \square \text{---} \\ | \\ \text{---} \bigcirc \text{---} \end{array} = \begin{array}{c} \text{---} \square \text{---} \\ | \\ \text{---} \bullet \text{---} \\ | \\ \text{---} \square \text{---} \end{array}$$

$$X = \text{---} \bullet_{\pi} \text{---} = \text{---} \square \text{---} \bigcirc_{\pi} \text{---} \square \text{---} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

$$S^{\dagger} = \text{---} \bigcirc_{-\pi/2} \text{---} = \text{---} \bigcirc_{\pi/2} \text{---} \bigcirc_{\pi/2} \text{---} \bigcirc_{\pi/2} \text{---}$$

$$\sqrt{X} = \text{---} \bullet_{\pi/4} \text{---} = \text{---} \square \text{---} \bigcirc_{\pi/2} \text{---} \square \text{---}$$

but not:

$$T = \text{---} \bigcirc_{\pi/4} \text{---}$$

$$TOF = CCX = \begin{array}{c} \text{---} \bullet \text{---} \\ | \\ \text{---} \bullet \text{---} \\ | \\ \text{---} \oplus \text{---} \end{array}$$

Why Clifford circuits interesting?

- contain useful states:

Bell 

C_{H2} 

- quantum error correction
- classical simulation efficient
- rich resource theory

Clifford diagrams is a ZX diagram made of "Clifford spiders"

notation:  $\rightsquigarrow$  "Hadamard edges"

a ZX diagram is graph-like if:

- all spiders are $\mathbb{Z}$ spiders
- all edges are Hadamard edges
- no parallel edges or self-loops
- every input/output is connected to spider

Clifford diagrams

Prop: every ZX diagram is equal to a graph-like one.

Proof: 1. use colour change to eliminate $\times$ spiders

2. use spider fusion to eliminate non-H edges

3. eliminate parallel edges:

eliminate self-loops:

4. use $\text{---} = \text{---} \circ$

Graph states with local Clifford operations

Graph states are graph-like ZX diagrams with no input

e.g.

but not

def: a graph state w local Cliffords ($|G\rangle$ S2C)
 is a state of form $(U_1 \otimes \dots \otimes U_n) |G\rangle$ for some
 graph G and 1-qubit Clifford gates U_i

Normal form

Def: a Clifford state is of form $|\psi\rangle = C|0\dots 0\rangle$ for some Clifford circuit C .

Thm any Clifford state is equal to a GSLC

Local complementation, pivoting

Local complementation of graph G about vertex u

is a new graph $G * u = (V, E')$ where V set of vertices
 $E \subseteq V \times V$ set of edges

$$\forall v, w \in N_G(u): \quad (v, w) \in E' \iff (v, w) \in E$$

↙
neighborhood

$$\text{and } E' \cap (V \setminus N_G(u)) \times V = E \cap (V \setminus N_G(u)) \times V$$

ex:

Prop: $\left\langle G \begin{matrix} u \\ \vdots \\ N(u) \end{matrix} \right\rangle = \left\langle G * u \begin{matrix} -\pi/2 \\ 0\pi/2 \\ 0\pi/2 \\ \vdots \end{matrix} \right\rangle$

Pivoting

consider strong complementarity:

add context:

deletes spiders.

deleted adjacent phase free spiders

pivot rule:

Simulating Clifford circuits

Simulation of Clifford circuits

given Clifford circuit C , compute $\text{Prob}(k_1, \dots, k_n \mid |\psi\rangle)$, where $|\psi\rangle = C|0 \dots 0\rangle$

use Born rule $\text{Prob}(k_1, \dots, k_n \mid |\psi\rangle) = |\langle k_1, \dots, k_n \mid C|0 \dots 0\rangle|^2$

algorithm: consider diagram D , run routine that "Clifford-simp":

1. convert to graph-like diagram
2. repeat until impossible: local complementation and pivoting
3. remove all isolated $\{0, \pi\}$ -spiders

prop: this terminates

Simulation of Clifford circuits

prop: algorithm terminates in polynomial time (in $\# \text{qubits}$ and $\# \text{gates of } C$)
 $G(n+k)$

remark this is not optimal: doing step 2 optimally takes $G(n^2k)$ steps
 if $k \gg n$, this makes a big difference

idea: 1. avoid big spiders: 

2. apply local complementation & pivoting left-to-right:

each step involves at most $O(n)$ spiders (hence $O(n^2)$ wires)

Synthesising Clifford circuits

Synthesis of Clifford circuits

Clifford diagram $\longrightarrow$ AP-form $\longrightarrow$ GSLC

all interior spiders
 - have phase $0, \pi$
 - are only connected to boundary spiders

no internal spiders

Synthesis of Clifford circuits

colour-change

Any Clifford circuit can be written with at most $O(n^4)$ gates.

Summary:

- ZX diagrams with phases $\pi/2$ are simulable but interesting
- Correspond to Clifford circuits
- Can bring to surprisingly efficient normal form graphically
- Can simulate efficiently graphically
