# Directed Graphical Models I Definition and Basic Properties

#### Chris Williams (based on slides by Michael U. Gutmann)

Probabilistic Modelling and Reasoning (INFR11134) School of Informatics, The University of Edinburgh

Spring Semester 2024

- We talked about reasonably weak assumption to facilitate the efficient representation of a probabilistic model
- Independence assumptions reduce the number of interacting variables, e.g.

$$p(\mathbf{x},\mathbf{y},\mathbf{z}) = p(\mathbf{x})p(\mathbf{y})p(\mathbf{z})$$

- $p(x_1,\ldots,x_d) = p(x_d|x_{d-3},x_{d-2},x_{d-1})p(x_1,\ldots,x_{d-1})$
- Parametric assumptions restrict the way the variables may interact.

# Chain rule

Iteratively applying the product rule allows us to factorise any joint pdf (pmf)  $p(\mathbf{x}) = p(x_1, x_2, \dots, x_d)$  into product of conditional pdfs.

$$p(\mathbf{x}) = p(x_1)p(x_2, \dots, x_d | x_1)$$
  
=  $p(x_1)p(x_2 | x_1)p(x_3, \dots, x_d | x_1, x_2)$   
=  $p(x_1)p(x_2 | x_1)p(x_3 | x_1, x_2)p(x_4, \dots, x_d | x_1, x_2, x_3)$   
:  
=  $p(x_1)p(x_2 | x_1)p(x_3 | x_1, x_2) \dots p(x_d | x_1, \dots x_{d-1})$   
=  $p(x_1) \prod_{i=2}^d p(x_i | x_1, \dots, x_{i-1})$   
=  $\prod_{i=1}^d p(x_i | \text{pre}_i)$ 

with  $\operatorname{pre}_i = \operatorname{pre}(x_i) = \{x_1, \ldots, x_{i-1}\}$ ,  $\operatorname{pre}_1 = \emptyset$  and  $p(x_1|\emptyset) = p(x_1)$ The chain rule can be applied to any ordering  $x_{k_1}, \ldots, x_{k_d}$ . Different orderings give different factorisations.

**PMR 2024** 

### Conditional independencies simplify the factors

- ► Given: a pdf/pmf that factorises as p(x) = ∏<sup>d</sup><sub>i=1</sub> p(x<sub>i</sub>|pre<sub>i</sub>) for the ordering x<sub>1</sub>,..., x<sub>d</sub>.
- For each x<sub>i</sub>, we condition on all previous variables in the ordering.
- Assume that, for each *i*, there is a minimal subset of variables  $\pi_i \subseteq \operatorname{pre}_i$  such that  $p(\mathbf{x})$  satisfies

$$x_i \perp (\operatorname{pre}_i \setminus \pi_i) \mid \pi_i$$

for all *i*.

- ► By definition of conditional independence:  $p(x_i|x_1,...,x_{i-1}) = p(x_i|\text{pre}_i) = p(x_i|\pi_i)$
- ▶ With the convention  $\pi_1 = \emptyset$ , we obtain the factorisation

$$p(x_1,\ldots,x_d)=\prod_{i=1}^d p(x_i|\pi_i)$$

#### Why does it matter?

▶ Denote the predecessors of  $x_i$  in the ordering by  $pre_i = \{x_1, \ldots, x_{i-1}\}$ , and let  $\pi_i \subseteq pre_i$ .

$$x_i \perp (\operatorname{pre}_i \setminus \pi_i) \mid \pi_i \text{ for all } \Longrightarrow p(\mathbf{x}) = \prod_{i=1}^d p(x_i \mid \pi_i)$$

#### What's the point?

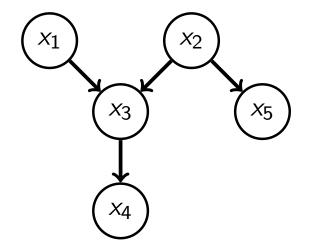

- 1.  $p(x_i|\pi_i)$  involve fewer interacting variables than  $p(x_i|\text{pre}_i)$ .
  - Makes them easier to model.
  - If specified as a table, fewer numbers are needed for their representation (computational advantage).
- 2. We can visualise the interactions between the variables with a graph.

## Visualisation as a directed graph

Assume  $p(\mathbf{x}) = \prod_{i=1}^{d} p(x_i | \pi_i)$  with  $\pi_i \subseteq \text{pre}_i$ . We visualise the model as a graph with the random variables  $x_i$  as nodes, and directed edges that point from the  $x_j \in \pi_i$  to the  $x_i$ . This results in a directed acyclic graph (DAG).

Example:

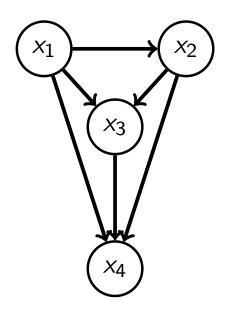

$$p(x_1, x_2, x_3, x_4, x_5) = p(x_1)p(x_2)p(x_3|x_1, x_2)p(x_4|x_3)p(x_5|x_2)$$

## Visualisation as a directed graph

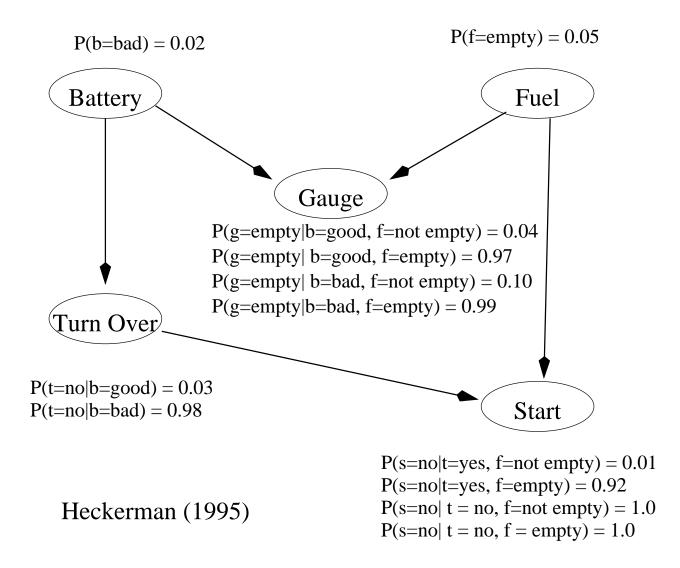

Example:

 $p(x_1, x_2, x_3, x_4) = p(x_1)p(x_2|x_1)p(x_3|x_1, x_2)p(x_4|x_1, x_2, x_3)$ 

Factorisation obtained by chain rule  $\equiv$  fully connected directed acyclic graph.

### Example: Car start belief network

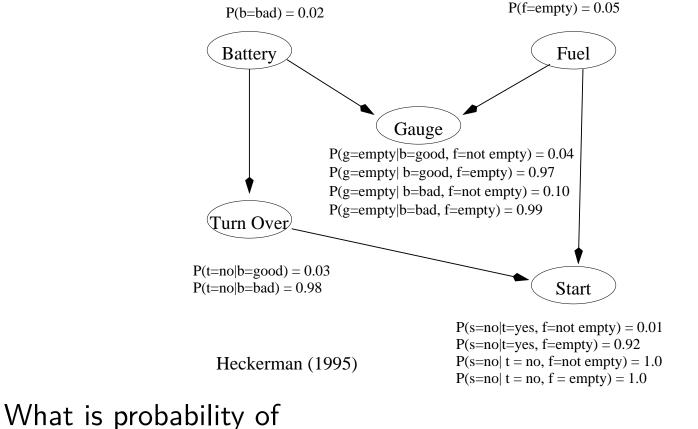

Unstructured joint distribution requires 2<sup>5</sup> - 1 = 31 numbers to specify it. Here can use 12 numbers
 Take the ordering b, f, g, t, s. Joint can be expressed as

p(b, f, g, t, s) = p(b)p(f|b)p(g|b, f)p(t|b, f, g)p(s|b, f, g, t)

Conditional independences (missing links) give

p(b, f, g, t, s) = p(b)p(f)p(g|b, f)p(t|b)p(s|t, f)

### Example: Car start belief network

p(b = good, t = no, g = empty, f = not empty, s = no)?

Let the x's be real-valued

$$p(x_i|\pi_i) = N(x_i|\mathbf{w}_i^T\mathbf{x}_{\pi_i} + b_i, \sigma_i^2)$$

- ▶  $p(\mathbf{x})$  is jointly Gaussian
- Exact inference can be carried out
  - (i) by first constructing the joint and conditioning, or
  - (ii) by exploiting the graphical structure
- Example: factor analysis (see later)

- 1. Choose a relevant set of variables  $\{x_i\}$  that describe the domain
- 2. Choose an ordering for the variables
- 3. While there are variables left
  - (a) Pick a variable  $x_i$  and add it to the network
  - (b) Set Parents(x<sub>i</sub>) to some minimal set of nodes already in the net
  - (c) Define the conditional probability table for  $x_i$

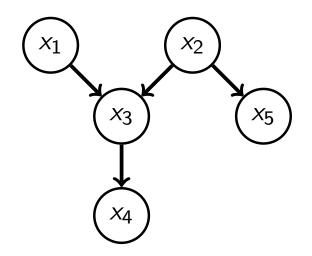

- This procedure is guaranteed to produce a DAG
- To ensure maximum sparsity, add "root causes" first, then the variables they influence and so on, until leaves are reached. Leaves have no direct causal influence over other variables
- Example: Construct DAG for the car example using the ordering s, t, g, f, b
- "Wrong" ordering will give same joint distribution, but will require the specification of more numbers than otherwise necessary

# Specifying conditional probability distributions

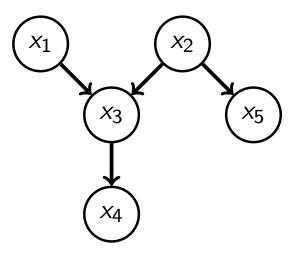

- CPDs: conditional probability distributions
- CPTs: conditional probability tables for discrete variables
- Where do the numbers come from? Can be elicited from experts, or learned (see later)
- CPTs can still be very large (and difficult to specify) if there are many parents for a node. Can use combination rules such as the logistic regression form

- Directed graph: graph where all edges are directed
- Directed acyclic graph (DAG): by following the direction of the arrows you will never visit a node more than once
- *x<sub>i</sub>* is a parent of *x<sub>j</sub>* if there is a (directed) edge from *x<sub>i</sub>* to *x<sub>j</sub>*. The set of parents of *x<sub>i</sub>* in the graph is denoted by pa(*x<sub>i</sub>*) = pa<sub>i</sub>, e.g. pa(*x*<sub>3</sub>) = pa<sub>3</sub> = {*x*<sub>1</sub>, *x*<sub>2</sub>}.

▶  $x_j$  is a child of  $x_i$  if  $x_i \in pa(x_j)$ , e.g.  $x_3$  and  $x_5$  are children of  $x_2$ .

- A path or trail from x<sub>i</sub> to x<sub>j</sub> is a sequence of distinct connected nodes starting at x<sub>i</sub> and ending at x<sub>j</sub>. The direction of the arrows does *not* matter. For example: x<sub>5</sub>, x<sub>2</sub>, x<sub>3</sub>, x<sub>1</sub> is a trail.
- A directed path is a sequence of connected nodes where we follow the direction of the arrows. For example: x<sub>1</sub>, x<sub>3</sub>, x<sub>4</sub> is a directed path. But x<sub>5</sub>, x<sub>2</sub>, x<sub>3</sub>, x<sub>1</sub> is not a directed path.

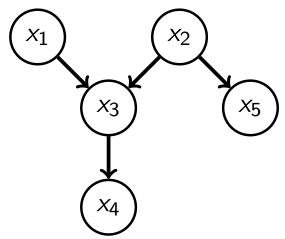

- The ancestors anc(x<sub>i</sub>) of x<sub>i</sub> are all the nodes where a directed path leads to x<sub>i</sub>. For example, anc(x<sub>4</sub>) = {x<sub>1</sub>, x<sub>3</sub>, x<sub>2</sub>}.
- The descendants desc(x<sub>i</sub>) of x<sub>i</sub> are all the nodes that can be reached on a directed path from x<sub>i</sub>. For example,

 $\operatorname{desc}(x_1) = \{x_3, x_4\}.$ 

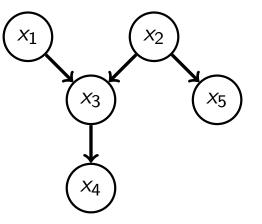

(Note: sometimes,  $x_i$  is included in the set of ancestors and descendants)

The non-descendents of x<sub>i</sub> are all the nodes in a graph except x<sub>i</sub> and the descendants of x<sub>i</sub>. For example,

nondesc $(x_3) = \{x_1, x_2, x_5\}$ 

- Topological ordering: an ordering (x<sub>1</sub>,...,x<sub>d</sub>) of some variables x<sub>i</sub> is topological relative to a graph if parents come before their children in the ordering. (whenever there is a directed edge from x<sub>i</sub> to x<sub>j</sub>, x<sub>i</sub> occurs prior to x<sub>j</sub> in the ordering.)
- Examples for the graph on the right:
  - $\blacktriangleright$   $x_1, x_2, x_3, x_4, x_5$
  - $\blacktriangleright$   $x_2, x_5, x_1, x_3, x_4$
  - $\blacktriangleright$   $x_2, x_1, x_3, x_5, x_4$

- There is always at least one ordering that is topological relative to a DAG.
- The  $\pi_i$  in the factorisation are equal to the parents  $pa_i$  in the graph. We will call both sets the "parents" of  $x_i$ .

  - Examples

# Directed graphical model (DGM)

- We started with a factorised pdf/pmf and associated a DAG with it.
- We can also go the other way around and start with a DAG.
- Definition A directed graphical model based on a DAG G with d nodes and associated random variables x<sub>i</sub> is the set of pdfs/pmfs that factorise as

$$p(x_1,\ldots,x_d) = \prod_{i=1}^d k(x_i|\mathrm{pa}_i)$$

where the  $k(x_i | pa_i)$  are some conditional pdfs/pmfs. (they are sometimes called kernels or factors)

Remark: a pdf/pmf p(x<sub>1</sub>,...,x<sub>d</sub>) that can be written as above is said to "factorise over the graph G". We also say that it has property F(G) ("F" for factorisation).

# Why set of pdfs/pmfs?

- The directed graphical model corresponds to a set of probability distributions.
- This is because we did not specify any numerical values for the k(x<sub>i</sub>|pa<sub>i</sub>). We only specified which variables the conditionals take as input (namely x<sub>i</sub> and pa<sub>i</sub>).
- The set includes all those distributions that you get by looping, for all variables x<sub>i</sub>, over all possible k(x<sub>i</sub>|pa<sub>i</sub>). (e.g. tables or parameter values in parametrised models)
- While a probability distribution corresponds to a probabilistic model, a set of probability distributions (probabilistic models) is often called a statistical model.
- Individual pdfs/pmf in the set are typically also called a directed graphical model.
- Other names for directed graphical models: belief network, Bayesian network, Bayes network.

# The factors $k(x_i | pa_i)$ equal the conditionals $p(x_i | pa_i)$

When we decomposed p(x) with the chain rule and inserted conditional independencies, we obtained

$$p(\mathbf{x}) = \prod_i p(x_i | \pi_i)$$

where the  $p(x_i|\pi_i)$  where the conditionals of  $x_i$  given  $\pi_i$ .

- We now show that the k(x<sub>i</sub>|pa<sub>i</sub>) in the definition of the DGM are equal to the p(x<sub>i</sub>|pa<sub>i</sub>).
- Assume p(x) factorises over a DAG G and hence that p(x) = ∏<sup>d</sup><sub>i=1</sub> k(x<sub>i</sub>|pa<sub>i</sub>). First step is to label the variables such that the ordering x<sub>1</sub>,..., x<sub>d</sub> is topological relative to G.
- In a topological ordering, the parents come before the children. Hence pa<sub>i</sub> ⊆ pre<sub>i</sub> = (x<sub>1</sub>,...,x<sub>i-1</sub>)

# The factors $k(x_i | pa_i)$ equal the conditionals $p(x_i | pa_i)$

• We next compute 
$$p(x_1, \ldots, x_{d-1})$$
 using the sum rule:

$$p(x_1, \dots, x_{d-1}) = \int p(x_1, \dots, x_d) dx_d$$
  
=  $\int \prod_{i=1}^d k(x_i | pa_i) dx_d$   
=  $\int \prod_{i=1}^{d-1} k(x_i | pa_i) k(x_d | pa_d) dx_d$  ( $x_d \notin pa_i, i < d$ )  
=  $\prod_{i=1}^{d-1} k(x_i | pa_i) \int k(x_d | pa_d) dx_d$   
=  $\prod_{i=1}^{d-1} k(x_i | pa_i)$ 

 $p(x_1,\ldots,x_d) = \prod_{i=1}^d k(x_i | \mathrm{pa}_i)$ 

The factors  $k(x_i | pa_i)$  equal the conditionals  $p(x_i | pa_i)$ 

Hence:

$$p(x_d|x_1,...,x_{d-1}) = \frac{p(x_1,...,x_d)}{p(x_1,...,x_{d-1})} = \frac{\prod_{i=1}^d k(x_i|pa_i)}{\prod_{i=1}^{d-1} k(x_i|pa_i)} = k(x_d|pa_d)$$

Split  $(x_1, \ldots, x_{d-1}) = \text{pre}_d$  into non-overlapping sets  $pa_d$  and  $\tilde{\mathbf{x}}_d = \text{pre}_d \setminus pa_d$  so that  $p(x_d | x_1, \ldots, x_{d-1}) = p(x_d | \tilde{\mathbf{x}}_d, pa_d)$ . By the product rule, we have

$$p(x_d, \tilde{\mathbf{x}}_d | \text{pa}_d) = p(x_d | \tilde{\mathbf{x}}_d, \text{pa}_d) p(\tilde{\mathbf{x}}_d | \text{pa}_d)$$
$$= k(x_d | \text{pa}_d) p(\tilde{\mathbf{x}}_d | \text{pa}_d)$$

Next sum out  $\tilde{\mathbf{x}}_d$  to obtain

$$\begin{split} p(x_d | \text{pa}_d) &= \int p(x_d, \tilde{\mathbf{x}}_d | \text{pa}_d) \text{d} \tilde{\mathbf{x}}_d = k(x_d | \text{pa}_d) \int p(\tilde{\mathbf{x}}_d | \text{pa}_d) \text{d} \tilde{\mathbf{x}}_d \\ &= k(x_d | \text{pa}_d) \end{split}$$

where we have used that  $x_d$  and  $pa_d$  are not part of  $\tilde{\mathbf{x}}_d$ .

The factors  $k(x_i | pa_i)$  equal the conditionals  $p(x_i | pa_i)$ Hence:

$$p(x_d|x_1,\ldots,x_{d-1}) = p(x_d|\operatorname{pa}_d) = k(x_d|\operatorname{pa}_d)$$

Next, note that  $p(x_1, \ldots, x_{d-1})$  has the same form as  $p(x_1, \ldots, x_d)$ : apply same procedure to all  $p(x_1, \ldots, x_k)$ , for smaller and smaller  $k \leq d-1$ 

Proves that for 
$$p(\mathbf{x}) = \prod_{i=1}^{d} k(x_i | pa_i)$$
:  
(1)  $k(x_i | pa_i) = p(x_i | pa_i)$  for  $i = 1, ..., d$   
(As desired!)  
(2)  $p(x_i | pre_i) = p(x_i | pa_i)$  for  $i = 1, ..., d$   
(This means that the factorisation of the DGM implies independencies, see later)  
(3)  $p(x_1, ..., x_k) = \prod_{i=1}^{k} k(x_i | pa_i)$  fo  $k = 1, ..., d$ 

(The distr of the first k variables is given by the first k terms in the factorisation)

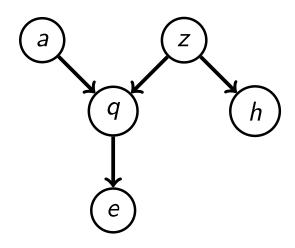

Note that (2) and (3) depend on the particular topological ordering chosen, e.g. it is "first k variables" in the chosen topological ordering.

### Ancestral sampling

- ► This means that the DAG not only specifies the joint distribution p(x) = ∏<sup>d</sup><sub>i=1</sub> k(x<sub>i</sub>|pa<sub>i</sub>) but also a sampling/data generating process.
- To generate data from  $p(\mathbf{x})$ :
  - 1. Pick an ordering  $x_1, \ldots, x_d$  of the random variables that is topological to G.
  - 2.  $x_1$  does not have any parents, i.e.  $pa_1 = \emptyset$ .
  - 3. Following the topological ordering, sample from  $k(x_i | pa_i)$ , i = 1, ..., d.
- Moreover, from the results above:
  - $\triangleright x_i | \mathrm{pa}_i \sim p(x_i | \mathrm{pa}_i)$ 
    - (The notation means that  $x_i$  follows or is sampled from  $p(x_i | pa_i)$ )
  - $(x_1, \ldots, x_k) \sim p(x_1, \ldots, x_k) \text{ for all } k$ (To e.g. sample from  $(x_1, x_2)$ , you can stop the sampling after i = 2.)
- It's called ancestral sampling because we sample the parents before the children, following the arrows in the DAG.

### Example

DAG:

Random variables: *a*, *z*, *q*, *e*, *h* 

 $\text{Parent sets: } \text{pa}_{\textit{a}} = \text{pa}_{\textit{z}} = \varnothing, \text{pa}_{\textit{q}} = \{\textit{a}, \textit{z}\}, \text{pa}_{\textit{e}} = \{\textit{q}\}, \text{pa}_{\textit{h}} = \{\textit{z}\}.$ 

Directed graphical model: set of pdfs/pmfs p(a, z, q, e, h) that factorise as:

$$p(a, z, q, e, h) = p(a)p(z)p(q|a, z)p(e|q)p(h|z)$$

#### Example: Markov chain

DAG:

Random variables:  $x_1, x_2, x_3, x_4, x_5$ 

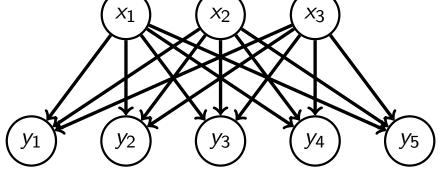

Parent sets:  $pa_1 = \emptyset, pa_2 = \{x_1\}, pa_3 = \{x_2\}, pa_4 = \{x_3\}, pa_5 = \{x_4\}.$ Directed graphical model: set of pdfs/pmfs  $p(x_1, \dots, x_5)$  that

factorise as:

$$p(\mathbf{x}) = p(x_1)p(x_2|x_1)p(x_3|x_2)p(x_4|x_3)p(x_5|x_4)$$

## Example: Probabilistic PCA, factor analysis, ICA

(PCA: principal component analysis; ICA: independent component analysis) DAG:  $(x_1)$   $(x_2)$   $(x_3)$ 

Random variables:  $x_1, x_2, x_3, y_1, \ldots, y_5$ 

Parent sets:  $pa(x_i) = \emptyset$ ,  $pa(y_i) = \{x_1, x_2, x_3\}$  for all *i*.

Directed graphical model: set of pdfs/pmfs  $p(x_1, x_2, x_3, y_1, \dots, y_5)$  that factorise as:

$$p(x_1, x_2, x_3, y_1, \dots, y_5) = p(x_1)p(x_2)p(x_3)p(y_1|x_1, x_2, x_3)$$
$$p(y_2|x_1, x_2, x_3) \dots p(y_5|x_1, x_2, x_3)$$
