

Reinforcement Learning

Value Function Approximation

Stefano V. Albrecht, Michael Herrmann

16 February 2024

THE UNIVERSITY *of* EDINBURGH
informatics

- Curse of dimensionality and generalisation
- Value function approximation
- Stochastic gradient descent
- Linear value functions and feature construction
- Semi-gradient TD control

Curse of Dimensionality

Theory so far has assumed:

- **Unlimited space:** can store value function as table
- **Unlimited data:** many (infinite) visits to all state-action pairs

In practice these assumptions are usually violated, because...

Curse of Dimensionality:

- Number of states grows *exponentially* with number of state variables
- If state described by k variables with values in $\{1, \dots, n\}$, then $O(n^k)$ states

Go: 10^{170} states

>

Hydrogen atoms: 10^{80}

Compact Value Functions and Generalisation

Two problems...

Compact Value Functions and Generalisation

Two problems...

Not enough memory to store value function as table

- Tabular $v(s)/q(s, a)$ use storage proportional to $|\mathcal{S}|$
- Need **compact representation** of value function

(But sometimes can be enough to store only partial value function; e.g. MCTS)

Compact Value Functions and Generalisation

Two problems...

Not enough memory to store value function as table

- Tabular $v(s)/q(s, a)$ use storage proportional to $|\mathcal{S}|$
- Need **compact representation** of value function
(But sometimes can be enough to store only partial value function; e.g. MCTS)

No data (or not enough data) to estimate return in each state

- Many states may never be visited
- Need to **generalise observations** to unknown state-action pairs

Generalisation

Blue circle must move to red goal

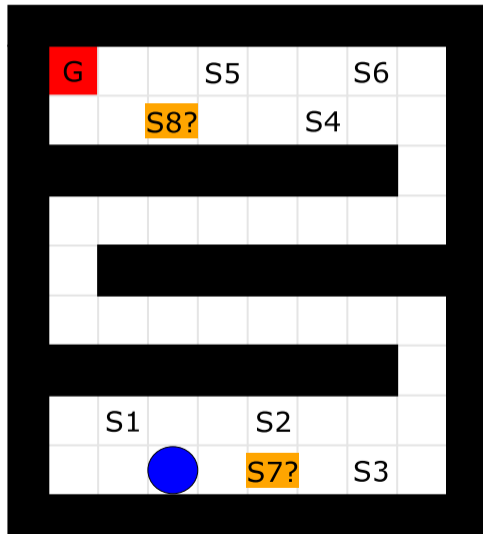

- Agent uses optimal policy (shortest path)

Suppose we have return estimates (steps to go) for locations S1–S6

- e.g. $v(S5) = -3$, $v(S4) = -6$, $v(S2) = -31$

We have no data for locations S7 and S8 (not visited yet)

- Can we estimate $v(S7)$ and $v(S8)$ based on other return estimates?

Value Function Approximation

Replace tabular value function with **parameterised function**:

$$\hat{v}(s, \mathbf{w}) \approx v_{\pi}(s)$$

$$\hat{q}(s, a, \mathbf{w}) \approx q_{\pi}(s, a)$$

$\mathbf{w} \in \mathbb{R}^d$ is parameter (“weight”) vector

e.g. linear function, neural network, regression tree, ...

- **Compact:** number of parameters d much smaller than $|\mathcal{S}|$
- **Generalises:** changing one parameter value may change value estimate of many states/actions

Supervised Learning

Learning a value function is a form of supervised learning:

Examples are pairs of states and return estimates, (S_t, U_t) , e.g.

- MC: $U_t = G_t$
- TD(0): $U_t = R_{t+1} + \gamma \hat{V}(S_{t+1}, \mathbf{w}_t)$
- n-step TD: $U_t = R_{t+1} + \dots + \gamma^{n-1} R_{t+n} + \gamma^n \hat{V}(S_{t+n}, \mathbf{w}_{t+n-1})$

Supervised Learning

Desired properties in supervised learning method:

- **Incremental updates**
update \mathbf{w} using only partial data, e.g. most recent (S_t, U_t) or subset

Supervised Learning

Desired properties in supervised learning method:

- **Incremental updates**
update \mathbf{w} using only partial data, e.g. most recent (S_t, U_t) or subset
- Ability to handle **noisy targets**
e.g. different MC updates G_t for same state S_t

Supervised Learning

Desired properties in supervised learning method:

- **Incremental updates**
update \mathbf{w} using only partial data, e.g. most recent (S_t, U_t) or subset
 - Ability to handle **noisy targets**
e.g. different MC updates G_t for same state S_t
 - Ability to handle **non-stationary targets**
e.g. changing target policy, bootstrapping
- ⇒ If \hat{v}/\hat{q} differentiable, **stochastic gradient descent** is suitable method

Gradient Descent

- Let $J(\mathbf{w})$ be differentiable function of \mathbf{w}
- Gradient of $J(\mathbf{w})$ is

$$\nabla J(\mathbf{w}) = \left(\frac{\partial J(\mathbf{w})}{\partial w_1}, \dots, \frac{\partial J(\mathbf{w})}{\partial w_d} \right)^\top$$

- To find local minimum of $J(\mathbf{w})$, adjust \mathbf{w} in negative direction of gradient

$$\mathbf{w}_{t+1} = \mathbf{w}_t - \frac{1}{2} \alpha \nabla J(\mathbf{w}_t)$$

- α is step-size parameter
convergence requires standard α -reduction

Stochastic Gradient Descent

Objective: find parameter vector \mathbf{w} by minimising *mean-squared error* between approximate value $\hat{v}(s, \mathbf{w})$ and true value $v_\pi(s)$

$$J(\mathbf{w}) = \mathbb{E}_\pi [(v_\pi(s) - \hat{v}(s, \mathbf{w}))^2]$$

Stochastic Gradient Descent

Objective: find parameter vector \mathbf{w} by minimising *mean-squared error* between approximate value $\hat{v}(s, \mathbf{w})$ and true value $v_\pi(s)$

$$J(\mathbf{w}) = \mathbb{E}_\pi [(v_\pi(s) - \hat{v}(s, \mathbf{w}))^2]$$

- Gradient descent finds local minimum:

$$\begin{aligned}\mathbf{w}_{t+1} &= \mathbf{w}_t - \frac{1}{2} \alpha \nabla J(\mathbf{w}_t) \\ &= \mathbf{w}_t + \alpha \mathbb{E}_\pi [(v_\pi(s) - \hat{v}(s, \mathbf{w}_t)) \nabla \hat{v}(s, \mathbf{w}_t)]\end{aligned}$$

Stochastic Gradient Descent

Objective: find parameter vector \mathbf{w} by minimising *mean-squared error* between approximate value $\hat{v}(s, \mathbf{w})$ and true value $v_\pi(s)$

$$J(\mathbf{w}) = \mathbb{E}_\pi [(v_\pi(s) - \hat{v}(s, \mathbf{w}))^2]$$

- Gradient descent finds local minimum:

$$\begin{aligned}\mathbf{w}_{t+1} &= \mathbf{w}_t - \frac{1}{2} \alpha \nabla J(\mathbf{w}_t) \\ &= \mathbf{w}_t + \alpha \mathbb{E}_\pi [(v_\pi(s) - \hat{v}(s, \mathbf{w}_t)) \nabla \hat{v}(s, \mathbf{w}_t)]\end{aligned}$$

- **Stochastic** gradient descent *samples* the gradient:

$$\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{v}(S_t, \mathbf{w}_t)] \nabla \hat{v}(S_t, \mathbf{w}_t)$$

Stochastic Gradient Descent — Convergence

Stochastic gradient descent *samples* the gradient:

$$\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{v}(S_t, \mathbf{w}_t)] \nabla \hat{v}(S_t, \mathbf{w}_t) \quad (1)$$

Stochastic Gradient Descent — Convergence

Stochastic gradient descent *samples* the gradient:

$$\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{v}(S_t, \mathbf{w}_t)] \nabla \hat{v}(S_t, \mathbf{w}_t) \quad (1)$$

- \mathbf{w}_t will converge to **local optimum** under standard α -reduction and if U_t is **unbiased estimate** $\mathbb{E}_\pi[U_t|S_t] = v_\pi(S_t)$
 \Rightarrow MC update is unbiased but TD update is biased (why?)

Stochastic Gradient Descent — Convergence

Stochastic gradient descent *samples* the gradient:

$$\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{v}(S_t, \mathbf{w}_t)] \nabla \hat{v}(S_t, \mathbf{w}_t) \quad (1)$$

- \mathbf{w}_t will converge to **local optimum** under standard α -reduction and if U_t is **unbiased estimate** $\mathbb{E}_\pi[U_t|S_t] = v_\pi(S_t)$
 \Rightarrow MC update is unbiased but TD update is biased (why?)
- Note: (1) is not a true TD gradient because U_t also depends on \mathbf{w}

$$U_t = R_{t+1} + \gamma \hat{v}(S_{t+1}, \mathbf{w})$$

Hence, we call it **semi-gradient** TD

Semi-gradient TD(0) for Policy Evaluation

Input: the policy π to be evaluated

Input: a differentiable function $\hat{v} : \mathcal{S}^+ \times \mathbb{R}^d \rightarrow \mathbb{R}$ such that $\hat{v}(\text{terminal}, \cdot) = 0$

Algorithm parameter: step size $\alpha > 0$

Initialize value-function weights $\mathbf{w} \in \mathbb{R}^d$ arbitrarily (e.g., $\mathbf{w} = \mathbf{0}$)

Loop for each episode:

 Initialize S

 Loop for each step of episode:

 Choose $A \sim \pi(\cdot | S)$

 Take action A , observe R, S'

$\mathbf{w} \leftarrow \mathbf{w} + \alpha [R + \gamma \hat{v}(S', \mathbf{w}) - \hat{v}(S, \mathbf{w})] \nabla \hat{v}(S, \mathbf{w})$

$S \leftarrow S'$

 until S is terminal

Linear value function approximation:

$$\hat{v}(s, \mathbf{w}) \doteq \mathbf{w}^\top \mathbf{x}(s) = \sum_{i=1}^d w_i x_i(s)$$

- $\mathbf{x}(s) = (x_1(s), \dots, x_d(s))^\top$ is *feature vector* of state s
- Simple gradient: $\nabla \hat{v}(s, \mathbf{w}) = \left(\frac{\partial \mathbf{w}^\top \mathbf{x}}{\partial w_1}, \dots, \frac{\partial \mathbf{w}^\top \mathbf{x}}{\partial w_d} \right)^\top = \mathbf{x}(s)$
- Gradient update: $\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{v}(S_t, \mathbf{w}_t)] \mathbf{x}(S_t)$

Linear value function approximation:

$$\hat{v}(s, \mathbf{w}) \doteq \mathbf{w}^\top \mathbf{x}(s) = \sum_{i=1}^d w_i x_i(s)$$

- $\mathbf{x}(s) = (x_1(s), \dots, x_d(s))^\top$ is *feature vector* of state s
- Simple gradient: $\nabla \hat{v}(s, \mathbf{w}) = \left(\frac{\partial \mathbf{w}^\top \mathbf{x}}{\partial w_1}, \dots, \frac{\partial \mathbf{w}^\top \mathbf{x}}{\partial w_d} \right)^\top = \mathbf{x}(s)$
- Gradient update: $\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{v}(S_t, \mathbf{w}_t)] \mathbf{x}(S_t)$

In linear case, there is only **one optimum!**

⇒ MC gradient updates converge to global optimum

⇒ TD gradient updates converge *near* global optimum (TD fixed point)

Feature Vectors

$$\mathbf{x}(s) = \begin{pmatrix} x\text{-pos}(s) \\ y\text{-pos}(s) \end{pmatrix}$$

$$\mathbf{x}(s) = \begin{pmatrix} \theta(s) \\ \theta\text{-vel}(s) \\ x\text{-pos}(s) \\ \vdots \end{pmatrix}$$

Remember:
State must be Markov

State Aggregation

Exact representation:

$$\mathbf{x}(s) = \begin{pmatrix} \text{x-pos}(s) \\ \text{y-pos}(s) \end{pmatrix}$$

Generalise with **state aggregation**:

- Partition states into disjoint sets $\mathcal{S}_1, \mathcal{S}_2, \dots$ with indicator functions $\mathbf{x}_k(s) = [s \in \mathcal{S}_k]_1$

$$\mathbf{x}(s) = \begin{pmatrix} \text{in-S1}(s) \\ \text{in-S2}(s) \\ \text{in-S3}(s) \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$$

State Aggregation

Exact representation:

$$\mathbf{x}(s) = \begin{pmatrix} \text{x-pos}(s) \\ \text{y-pos}(s) \end{pmatrix}$$

Generalise with **state aggregation**:

- Partition states into disjoint sets $\mathcal{S}_1, \mathcal{S}_2, \dots$ with indicator functions $\mathbf{x}_k(s) = [s \in \mathcal{S}_k]_1$

Special case: every state s has its own set $\mathcal{S}_s = \{s\}$

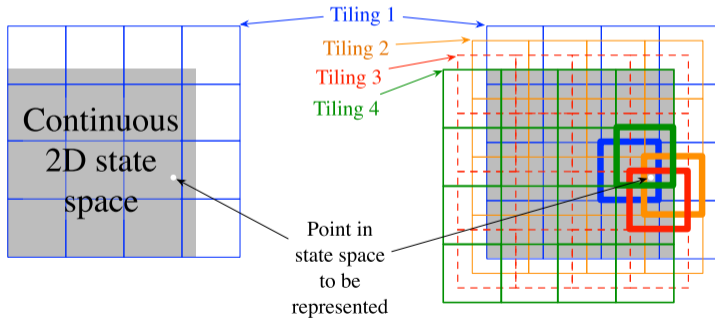

⇒ **Same as tabular representation!**

Coarse/Tile Coding

State aggregation generalises only within sets $\mathcal{S}_1, \mathcal{S}_2, \dots$

- Allow generalisation *across* sets by allowing \mathcal{S}_k to overlap
- e.g. **coarse coding** and **tile coding**

Example: Random Walk

- States: numbered 1 to 1000, start at state 500
- Policy: randomly jump to one of 100 states to left, or one of 100 states to right
- If jump goes beyond 1/1000, terminates with reward $-1/+1$
- State aggregation: 10 groups of 100 states each

Random Walk: MC and TD Prediction

Linear gradient MC:

Linear gradient TD:

After 100,000 episodes with $\alpha = 2 \times 10^{-5}$

Approximate Control in Episodic Tasks

- Estimate state-action values: $\hat{q}(s, a, \mathbf{w}) \approx q_{\pi}(s, a)$
- For linear approx., features defined over states *and* action:

$$\hat{q}(s, a, \mathbf{w}) \doteq \sum_{i=1}^d w_i x_i(s, a)$$

- Stochastic gradient descent:

$$\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{q}(S_t, A_t, \mathbf{w}_t)] \nabla \hat{q}(S_t, A_t, \mathbf{w}_t)$$

Approximate Control in Episodic Tasks

- Estimate state-action values: $\hat{q}(s, a, \mathbf{w}) \approx q_\pi(s, a)$
- For linear approx., features defined over states *and* action:

$$\hat{q}(s, a, \mathbf{w}) \doteq \sum_{i=1}^d w_i x_i(s, a)$$

- Stochastic gradient descent:

$$\mathbf{w}_{t+1} = \mathbf{w}_t + \alpha [U_t - \hat{q}(S_t, A_t, \mathbf{w}_t)] \nabla \hat{q}(S_t, A_t, \mathbf{w}_t)$$

e.g. **Sarsa**: $U_t = R_{t+1} + \gamma \hat{q}(S_{t+1}, A_{t+1}, \mathbf{w}_t)$

Q-learning: $U_t = R_{t+1} + \gamma \max_a \hat{q}(S_{t+1}, a, \mathbf{w}_t)$

Expected Sarsa: $U_t = R_{t+1} + \gamma \sum_a \pi(a|S_{t+1}) \hat{q}(S_{t+1}, a, \mathbf{w}_t)$

Episodic Semi-gradient Sarsa

Input: a differentiable action-value function parameterization $\hat{q} : \mathcal{S} \times \mathcal{A} \times \mathbb{R}^d \rightarrow \mathbb{R}$

Algorithm parameters: step size $\alpha > 0$, small $\varepsilon > 0$

Initialize value-function weights $\mathbf{w} \in \mathbb{R}^d$ arbitrarily (e.g., $\mathbf{w} = \mathbf{0}$)

Loop for each episode:

$S, A \leftarrow$ initial state and action of episode (e.g., ε -greedy)

 Loop for each step of episode:

 Take action A , observe R, S'

 If S' is terminal:

$$\mathbf{w} \leftarrow \mathbf{w} + \alpha [R - \hat{q}(S, A, \mathbf{w})] \nabla \hat{q}(S, A, \mathbf{w})$$

 Go to next episode

 Choose A' as a function of $\hat{q}(S', \cdot, \mathbf{w})$ (e.g., ε -greedy)

$$\mathbf{w} \leftarrow \mathbf{w} + \alpha [R + \gamma \hat{q}(S', A', \mathbf{w}) - \hat{q}(S, A, \mathbf{w})] \nabla \hat{q}(S, A, \mathbf{w})$$

$S \leftarrow S'$

$A \leftarrow A'$

Example: Mountain Car with Linear Semi-Gradient Sarsa

STATES:

car's position and velocity

ACTIONS:

three thrusts: forward, reverse, none

REWARDS:

always -1 until car reaches the goal

Episodic, No Discounting, $\gamma=1$

Semi-gradient Sarsa with linear approximation over 8 8x8 tilings
 $\epsilon = 0$ (optimistic initial values $\hat{q}(s, a, \mathbf{w}) = 0$)

Learned Action Values in Mountain Car

MOUNTAIN CAR Goal

Cost-to-go:
– $\max_a \hat{q}(s, a, w)$

Learning Curves in Mountain Car

Mountain Car
Steps per episode
log scale
averaged over 100 runs

Convergence to Global Optimum in Episodic Control

Algorithm	Tabular	Linear	Non-linear
MC control	yes	chatter*	no
(semi-gradient) n-step Sarsa	yes	chatter*	no
(semi-gradient) n-step Q-learning	yes	no	no

*Chatters near optimal solution because optimal policy may not be representable under value function approximation

Risk of divergence arises when the following three are combined:

1. Function approximation
2. Bootstrapping
3. Off-policy learning

Possible fixes:

- Use importance sampling to warp off-policy distribution into on-policy distribution
- Use gradient TD methods which follow true gradient of projected Bellman error (see book)

Required (RL book):

- Chapter 9 (9.1–9.5)
(Box “Proof of Convergence of Linear TD(0)” in Sec 9.4 is not examined)
- Chapter 10 (10.1)
- Chapter 11 (11.1)
