How to participate?

Planning and Monitoring the Process

08/10/2024

Updated by Stuart Anderson (c) 2007 Mauro Pezzè & Michal Young

Ch 20, slide 2

Learning objectives

- Be able to explain the role of monitoring in planning
- Be able to distinguish strategies from plans and illustrate how a plan is derived from a strategy
- Given a plan be able to provide examples of risks arising in plans
- Given a quality process, be able to identify the role of monitoring in the quality process
- Be able to explain the role of team organization in planning

What are Planning and Monitoring?

- Planning:
 - Scheduling activities (what steps? in what order?)
 - Allocating resources (who will do it?)
 - Devising clear milestones for monitoring
- Monitoring: Measuring key process attributes of the process
 - What do the measures tell about progress against the plan?
- A good plan must have *visibility* :
 - Ability to monitor key indicators, and to make informed judgments of progress against the plan
 - Ability to justify where we are in the plan and what progress has been made.

Quality and Process

- Quality process: Set of activities and responsibilities
 - focused primarily on ensuring adequate quality
 - concerned with project schedule or with product usability
- A framework for
 - selecting and arranging activities
 - considering interactions and trade-offs
- Follows the overall software process in which it is embedded
 - Example: waterfall software process —> "V model": unit testing starts with implementation and finishes before integration
 - Example: XP and agile methods —> emphasis on unit testing and rapid iteration for acceptance testing by customers
 - Example: DevOps CI/CD includes elements of validation as data is collected from operation

Example Process: Cleanroom

Overall Organization of a Quality Process

- Key principle of quality planning
 - the cost of detecting and repairing a fault increases as a function of time between creating the fault and detecting it (e.g the time is zero if we are perfect)
- therefore ...
 - an efficient quality plan includes matched sets of *intermediate* validation and verification activities that *detect most important faults within a short time* of their introduction [limits on resource mean we need to focus on important faults]
- and ...
 - V&V steps depend on the intermediate work products and on their *anticipated defects*

Verification Steps for Intermediate Artifacts

• Internal consistency checks

- compliance with structuring rules that define "well-formed" artifacts of that type
- a point of leverage: define syntactic and semantic rules thoroughly and precisely enough that many common errors result in detectable violations
- Structural rules + frameworks can often simplify the testing of software
- External consistency checks
 - consistency with related artifacts
 - Often: conformance to a "prior" or "higher-level" specification
- Generation of correctness conjectures
 - Correctness conjectures: lay the groundwork for external consistency checks of other work
 products
 - Often: motivate refinement of the current product

Strategies vs Plans

	Strategy	Plan
Scope	Organization	Project
Structure and content based on	Organization structure, experience and policy over several projects	Standard structure prescribed in strategy
Evolves	Slowly, with organization and policy changes	Quickly, adapting to project needs

Test and Analysis Strategy

- Lessons of past experience
 - an organizational asset built and refined over time particularly if the organization develops a line of similar products
- Body of explicit knowledge
 - more valuable than islands of individual competence or tacit knowledge
 - amenable to improvement
 - reduces vulnerability to organizational change (e.g., loss of key individuals)
- Essential for
 - avoiding recurring errors
 - maintaining consistency of the process
 - increasing development efficiency

Fitting a Strategy to an Organization

• Structure and size

- example
 - Distinct quality groups in large organizations, overlapping of roles in smaller organizations
 - greater reliance on documents in large than small organizations
- Overall process
 - example
 - Cleanroom requires statistical testing and forbids unit testing
 - fits with tight, formal specs and emphasis on reliability
 - XP prescribes "test first" and pair programming
 - fits with fluid specifications and rapid evolution
- Application domain
 - example
 - Safety critical domains may impose particular quality objectives and require documentation for certification (e.g,RTCA/DO-178B standard requires MC/DC coverage a particular type of structural test)

Elements of a Strategy

- Common quality requirements that apply to all or most products
 - clear definition and measures
- Set of documents normally produced during the quality process
 - contents and relationships
- Activities prescribed by the overall process
 - standard tools and practices
- Guidelines for project staffing and assignment of roles and responsibilities
- See technical debt: <u>https://en.wikipedia.org/wiki/Technical_debt</u> strategies typically try to avoid this

Test and Analysis Plan

Answer the following questions:

- What quality activities will be carried out?
- What are the dependencies among the quality activities and between quality and other development activities?
- What resources are needed and how will they be allocated?
- How will both the process and the product be monitored?
- There can be considerable variability in the order in which activities are carried out as long as the dependencies are respected.

Main Elements of a Plan

- Items and features to be verified
 - Scope and target of the plan
- Activities and resources
 - Constraints imposed by resources on activities
- Approaches to be followed
 - Methods and tools
- Criteria for evaluating results

Quality Goals

- Expressed as properties satisfied by the product
 - must include metrics to be monitored during the project
 - *example:* a new release of the product must undergo canary testing with successively larger populations before full release
 - not all details are available in the early stages of development
- Initial plan
 - based on incomplete information
 - incrementally refined

Task Schedule

- Initially based on
 - quality strategy
 - past experience
- Breaks large tasks into subtasks
 - refine as process advances
- Includes dependencies
 - among quality activities
 - between quality and development activities
- Guidelines and objectives:
 - schedule activities for steady effort and continuous progress and evaluation without delaying development activities
 - schedule activities as early as possible
 - increase process visibility (how do we know we're on track?)

Sample Schedule

	ID Task Name	Dec 2006	Jan 2007	Feb 2007	Mar 2007	Apr 2007
1	CRITICAL SCHEDULE					
2	Project start	•				
3	Analysis and design	l≁ I				
4	Code and integration		+			
5	Design and execute subsystem tests				→	
6	Design and execute system tests					
7	Produce user documentation		→			
8	Product delivery					•

Sample Schedule

Sample Schedule

19	LIMITED RESOURCES	
20	Project start	
21	Analysis and design	
22	Code and integration	
23	Design subsystem tests	
24	Design system tests	
25	Produce user documentation	
26	Execute subystem tests	┝▇」
27	Execute system tests	
28	Product delivery	

Schedule Risk

- critical path = chain of activities that must be completed in sequence and that have maximum overall duration
 - Schedule critical tasks and tasks that depend on critical tasks as early as possible to
 - provide schedule slack
 - prevent delay in starting critical tasks
- critical dependence = task on a critical path scheduled immediately after some other task on the critical path
 - May occur with tasks outside the quality plan (part of the project plan)
 - Reduce critical dependences by decomposing tasks on critical path, factoring out subtasks that can be performed earlier

Reducing the Impact of Critical Paths

Task name	January	Febrary	March	April	May	
CRITICAL SCHEDULE						
Project start						
Analysis and design						
Code and integration						
Design and execute subsystem tests				*		
Design and execute system tests						
Produce user documentation		▼				
Product delivery						

Reducing the Impact of Critical Paths

Task name	January	Febrary	March	April	May	
UNLIMITED RESOURCES						
Project start						
Analysis and design						
Code and integration						
Design subsystem tests						
Design system tests						
Produce user documentation						
Execute subsystem tests						
Execute system tests						
Product delivery						

Reducing the Impact of Critical Paths

Task name	January	Febrary	March	April	May	
LIMITED RESOURCES						
Project start						
Analysis and design	•					
Code and integration						
Design subsystem tests						
Design system tests						
Produce user documentation						
Execute subsystem tests				•		
Execute system tests						
Product delivery					-	

Risk Planning

- Risks cannot be eliminated, but they can be assessed, controlled, and monitored
- Generic management risk
 - Personnel (or more generally resource)
 - Technology
 - Schedule
- Quality risk
 - Development
 - Execution
 - Requirements

Personnell

Example Risks

- Loss of a staff member
- Staff member under-qualified for task

- cross training to avoid overdependence on individuals
- continuous education
- identification of skills gaps early in project
- competitive compensation and promotion policies and rewarding work
- including training time in project schedule

Technology

Example Risks

- High fault rate due to unfamiliar COTS component interface
- Test and analysis automation tools do not meet expectations

- Anticipate and schedule extra time for testing unfamiliar interfaces.
- Invest training time for COTS components and for training with new tools
- Monitor, document, and publicize common errors and correct idioms.
- Introduce new tools in lower-risk pilot projects or prototyping exercises

Schedule

Example Risks

- Inadequate unit testing leads to unanticipated expense and delays in integration testing
- Difficulty of scheduling meetings makes inspection a bottleneck in development

- Track and reward quality unit testing as evidenced by low fault densities in integration
- Set aside times in a weekly schedule in which inspections take precedence over other meetings and work
- Try distributed and asynchronous inspection techniques, with a lower frequency of face-to-face inspection meetings

Development

Example Risks

- Poor quality software delivered to testing group
- Inadequate unit test and analysis before committing to the code base

- Provide early warning and feedback
- Schedule inspection of design, code and test suites
- Connect development and inspection to the reward system
- Increase training through inspection
- Require coverage or other criteria at unit test level

Test Execution

Example Risks

- Execution costs higher than planned
- Scarce resources available for testing

- Minimize parts that require full system to be executed
- Inspect architecture to assess and improve testability
- Increase intermediate feedback
- Invest in scaffolding

Requirements

Example Risk

 High assurance critical requirements increase expense and uncertainty

- Compare planned testing effort with former projects with similar criticality level to avoid underestimating testing effort
- Balance test and analysis
- Isolate critical parts, concerns and properties

Contingency Plan

- Part of the initial plan
 - What could go wrong? How will we know, and how will we recover?
- Evolves with the plan
- Derives from risk analysis
 - Essential to consider risks explicitly and in detail
- Defines actions in response to bad news
 - Plan B at the ready (the sooner, the better)

Evolution of the Plan

Process Monitoring

- Identify deviations from the quality plan as early as possible and take corrective action
- Depends on a plan that is
 - realistic
 - well organized
 - sufficiently detailed with clear, unambiguous milestones and criteria
- A process is visible to the extent that it can be effectively monitored

Evaluate Aggregated Data by Analogy

Process Improvement

Monitoring and improvement within a project or across multiple projects:

- Orthogonal Defect Classification (ODC)
- Root Cause Analysis (RCA)

Orthogonal Defect Classification (ODC)

• Accurate classification schema

- for very large projects
- to distill an unmanageable amount of detailed information
- Two main steps
 - Fault classification
 - when faults are detected
 - when faults are fixed
 - Fault analysis

ODC Fault Classification

- When faults are detected
 - *activity* executed when the fault is revealed
 - trigger that exposed the fault
 - *impact* of the fault on the customer
- When faults are fixed
 - *Target:* entity fixed to remove the fault
 - *Type:* type of the fault
 - *Source:* origin of the faulty modules (in-house, library, imported, outsourced)
 - Age of the faulty element (new, old, rewritten, re-fixed code)

ODC activities and triggers

Review and Code Inspection

- Design Conformance:
- Logic/Flow
- Backward Compatibility
- Internal Document
- Lateral Compatibility
- Concurrency
- Language Dependency
- Side Effects
- Rare Situation

Structural (White Box) Test

- Simple Path
- Complex Path

Functional (Black box) Test

- Coverage
- Variation
- Sequencing
- Interaction

System Test

- Workload/Stress
- Recovery/Exception
- Startup/Restart
- Hardware Configuration
- Software Configuration
- Blocked Test

ODC impact

- Installability
- Integrity/Security
- Performance
- Maintenance
- Serviceability
- Migration
- Documentation

- Usability
- Standards
- Reliability
- Accessibility
- Capability
- Requirements

ODC Fault Analysis (example 1/4)

- Distribution of fault types versus activities
 - Different quality activities target different classes of faults
 - Example:
 - algorithmic faults are targeted primarily by unit testing.
 - Expect a high proportion of faults detected by unit testing should belong to this class
 - IF proportion of algorithmic faults found during unit testing is:
 - unusually small OR larger than normal found at integration test
 - THEN unit tests may not have been well designed
 - IF proportion of algorithmic faults found during integration testing unusually large
 - THEN integration testing may not focus strongly enough on interface faults

ODC Fault Analysis (example 2/4)

- Distribution of triggers over time during field test
 - Faults corresponding to simple usage should arise early during field test, while faults corresponding to complex usage should arise late.
 - The rate of disclosure of new faults should asymptotically decrease
 - Unexpected distributions of triggers over time may indicate poor system or acceptance test
 - IF triggers that correspond to simple usage reveal many faults late in acceptance testing THEN sample may not be representative of the user population
 - IF continuously growing faults during acceptance test is observed THEN system testing may have failed

ODC Fault Analysis (example 3/4)

- Age distribution over target code
 - Most faults should be located in new and rewritten code
 - The proportion of faults in new and rewritten code with respect to base and re-fixed code should gradually increase
- Different age distributions
 - may indicate holes in the fault tracking and removal process
 - may indicate inadequate test and analysis that failed in revealing faults early
 - Example
 - increase of faults located in base code after porting may indicate inadequate tests for portability

ODC Fault Analysis (example 4/4)

- Distribution of fault classes over time
 - The proportion of missing code faults should gradually decrease (because the code is being provided)
 - The percentage of extraneous faults may slowly increase, because missing functionality should be revealed with use and repaired.
 - Examples:
 - An increasing number of missing faults may be a symptom of instability of the product.
 - A sudden sharp increase in extraneous faults may indicate maintenance problems

Improving the Process

- Many classes of faults that occur frequently are rooted in process and development flaws
 - examples
 - Shallow architectural design that does not take into account resource allocation can lead to resource allocation faults
 - Lack of experience with the development environment, which leads to misunderstandings between analysts and programmers on rare and exceptional cases, can result in faults in exception handling.
- The occurrence of many such faults can be reduced by modifying the process and environment
 - examples
 - Resource allocation faults resulting from shallow architectural design can be reduced by introducing specific inspection tasks
 - Faults attributable to inexperience with the development environment can be reduced with focused training

Improving Current and Next Processes

- Identifying weak aspects of a process can be difficult
- Analysis of the fault history can help software engineers build a feedback mechanism to track relevant faults to their root causes
 - Sometimes information can be fed back directly into the current product development
 - More often it helps software engineers improve the development of future products

Root cause analysis (RCA)

- Technique for identifying and eliminating process faults
 - First developed in the nuclear power industry; used in many fields.
- Four main steps
 - What are the faults?
 - When did faults occur? When, and when were they found?
 - Why did faults occur?
 - *How* could faults be prevented?

What are the faults?

- Identify a class of important faults
- Faults are categorized by
 - severity = impact of the fault on the product
 - Kind
 - No fixed set of categories; Categories evolve and adapt
 - Goal:
 - Identify the few most important classes of faults and remove their causes
 - Differs from ODC: Not trying to compare trends for different classes of faults, but rather *focusing* on a few important classes

Fault Severity

Level	Description	Example
Critical	The product is unusable	The fault causes the program to crash
Severe	Some product features cannot be used, and there is no workaround	The fault inhibits importing files saved with a previous version of the program, and there is no workaround
Moderate	Some product features require workarounds to use, and reduce efficiency, reliability, or convenience and usability	The fault inhibits exporting in Postscript format. Postscript can be produced using the printing facility, but with loss of usability and efficiency
Cosmetic	Minor inconvenience	The fault limits the choice of colors for customizing the graphical interface, violating the specification but causing only minor inconvenience

Pareto Distribution (80/20)

- Pareto rule (80/20)
 - in many populations, a few (20%) are vital and many (80%) are trivial
- Fault analysis
 - 20% of the code is responsible for 80% of the faults
 - Faults tend to accumulate in a few modules
 - identifying potentially faulty modules can improve the cost effectiveness of fault detection
 - Some classes of faults predominate
 - removing the causes of a predominant class of faults can have a major impact on the quality of the process and of the resulting product

Why did faults occur?

- Core RCA step
 - trace representative faults back to causes
 - objective of identifying a "root" cause
- Iterative analysis
 - explain the error that led to the fault
 - explain the cause of that error
 - explain the cause of that cause
 - ...
- Rule of thumb
 - "ask why six times"

Example of fault tracing

- Tracing the causes of faults requires experience, judgment, and knowledge of the development process
- example
 - most significant class of faults = memory leaks
 - cause = forgetting to release memory in exception handlers
 - cause = lack of information: "Programmers can't easily determine what needs to be cleaned up in exception handlers"
 - cause = design error: "The resource management scheme assumes normal flow of control"
 - root problem = early design problem: "Exceptional conditions were an afterthought dealt with late in design"

How could faults be prevented?

- Many approaches depending on fault and process:
- From lightweight process changes
 - example
 - adding consideration of exceptional conditions to a design inspection checklist
- To heavyweight changes:
 - example
 - making explicit consideration of exceptional conditions a part of all requirements analysis and design steps
- Goal is not perfection, but cost-effective improvement (excellence is the enemy of the good)

The Quality Team

- The quality plan must assign roles and responsibilities to people
- assignment of responsibility occurs at
 - strategic level
 - test and analysis strategy
 - structure of the organization
 - external requirements (e.g., certification agency)
 - tactical level
 - test and analysis plan

Roles and Responsibilities at Tactical Level

- balance level of effort across time
- manage personal interactions
- ensure sufficient accountability that quality tasks are not easily overlooked
- encourage objective judgment of quality
- prevent it from being subverted by schedule pressure
- foster shared commitment to quality among all team members
- develop and communicate shared knowledge and values regarding quality

Alternatives in Team Structure

- Conflicting pressures on choice of structure
 - example
 - autonomy to ensure objective assessment
 - cooperation to meet overall project objectives
- Different structures of roles and responsibilities
 - same individuals play roles of developer and tester
 - most testing responsibility assigned to a distinct group
 - some responsibility assigned to a distinct organization
- Distinguish
 - oversight and accountability for approving a task
 - responsibility for actually performing a task

Roles and responsibilities pros and cons

- Same individuals play roles of developer and tester
 - potential conflict between roles
 - example
 - a developer responsible for delivering a unit on schedule
 - responsible for integration testing that could reveal faults that delay delivery
 - requires countermeasures to control risks from conflict
- Roles assigned to different individuals
 - Potential conflict between individuals
 - example
 - developer and a tester who do not share motivation to deliver a quality product on schedule
 - requires countermeasures to control risks from conflict

Independent Testing Team

- Minimize risks of conflict between roles played by the same individual
 - Example
 - project manager with schedule pressures cannot
 - bypass quality activities or standards
 - reallocate people from testing to development
 - postpone quality activities until too late in the project
- Increases risk of conflict between goals of the independent quality team and the developers
- Plan
 - should include checks to ensure completion of quality activities
 - Example
 - developers perform module testing
 - independent quality team performs integration and system testing
 - quality team should check completeness of module tests

Managing Communication

- Testing and development teams must share the goal of shipping a high-quality product on schedule
 - testing team
 - must not be perceived as relieving developers from responsibility for quality
 - should not be completely oblivious to schedule pressure
- Independent quality teams require a mature development process
 - Test designers must
 - work on sufficiently precise specifications
 - execute tests in a controllable test environment
- Versions and configurations must be well defined
- Failures and faults must be suitably tracked and monitored across versions

Testing within XP

- Full integration of quality activities with development
 - Minimize communication and coordination overhead
 - Developers take full responsibility for the quality of their work
 - Technology and application expertise for quality tasks match expertise available for development tasks
- Plan
 - check that quality activities and objective assessment are not easily tossed aside as deadlines loom
 - example
 - XP "test first" together with pair programming guard against some of the inherent risks of mixing roles

Outsourcing Test and Analysis

• (Wrong) motivation

- testing is less technically demanding than development and can be carried out by lower-paid and lower-skilled individuals
- Why wrong
 - confuses test execution (straightforward) with analysis and test design (as demanding as design and programming)
- A better motivation
 - to maximize independence
 - and possibly reduce cost as (only) a secondary effect
- The plan must define
 - milestones and delivery for outsourced activities
 - checks on the quality of delivery in both directions

Summary

- Planning is necessary to
 - order, provision, and coordinate quality activities
 - coordinate quality process with overall development
 - includes allocation of roles and responsibilities
 - provide unambiguous milestones for judging progress
- Process visibility is key
 - ability to monitor quality and schedule at each step
 - intermediate verification steps: because cost grows with time between error and repair
 - monitor risks explicitly, with contingency plan ready
- Monitoring feeds process improvement
 - of a single project, and across projects
